Functional Description

The CY7C1021BN is a high performance CMOS static RAM organized as 65,536 words by 16 bits. This device has an automatic power down feature that significantly reduces power consumption when deselected.

Writing to the device is accomplished by taking Chip Enable (\overline{CE}) and Write Enable (WE) inputs LOW. If Byte Low Enable (BLE) is LOW, then data from the input/output (I/O) pins (I/O₁ through I/O₈), is written into the location specified on the address pins (A₀ through A₁₅). If Byte High Enable (BHE) is LOW, then data from I/O pins (I/O₉ through I/O₁₆) is written into the location specified on the address pins (A₀ through A₁₅).

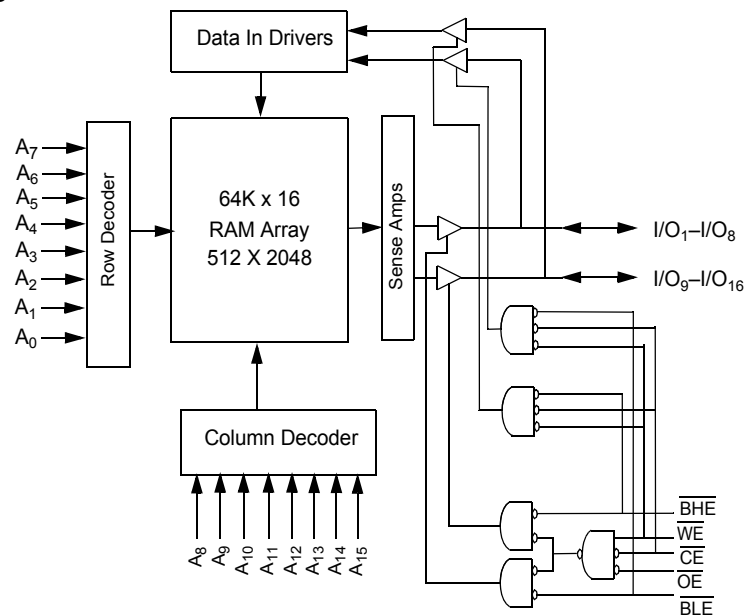

Reading from the device is accomplished by taking \overline{CE} and Output Enable (OE) LOW while forcing WE HIGH. If BLE is LOW, then data from the memory location specified by the address pins appears on I/O₁ to I/O₈. If BHE is LOW, then data from memory appears on I/O₉ to I/O₁₆. See the Truth Table on page 11 for a complete description of read and write modes.

The I/O pins (I/O₁ through I/O₁₆) are placed in a high impedance state when the device is deselected (\overline{CE} HIGH), the outputs are disabled (OE HIGH), the BHE and BLE are disabled (BHE, BLE HIGH), or during a write operation (\overline{CE} LOW, WE LOW).

The CY7C1021BN is available in standard 44-pin TSOP type II and 44-pin 400-mil-wide SOJ packages. Use part number CY7C1021BN when ordering 15 ns t_{AA} .

Notes

- Test conditions assume signal transition time of 3 ns or less, timing reference levels of 1.5 V, input pulse levels of 0 to 3.0 V, and output loading of the specified I_{OL}/I_{OH} and 30 pF load capacitance.
- At any temperature and voltage condition, t_{HZCE} is less than t_{LZCE} , t_{HZOE} is less than t_{LZOE} , t_{HZBE} is less than t_{LZBE} , and t_{HZWE} is less than t_{LZWE} for any device.
- t_{HZOE} , t_{HZBE} , t_{HZCE} , and t_{HZWE} are specified with a load capacitance of 5 pF as in part (b) of Figure 2 on page 6. Transition is measured ± 500 mV from steady-state voltage.
- The internal write time of the memory is defined by the overlap of \overline{CE} LOW, \overline{WE} LOW, and $\overline{BHE} / \overline{BLE}$ LOW. \overline{CE} , \overline{WE} , and $\overline{BHE} / \overline{BLE}$ must be LOW to initiate a write, and the transition of these signals can terminate the write. The input data setup and hold timing should be referenced to the leading edge of the signal that terminates the write.
- The minimum write cycle pulse width for the Write Cycle No. 3 (\overline{WE} Controlled, \overline{OE} LOW) should be equal to sum of t_{SD} and t_{HZWE} .

Switching Waveforms

Notes

- 9. Device is continuously selected. \overline{OE} , \overline{CE} , \overline{BHE} , and \overline{BLE} = V_{IL} .
- 10. WE is HIGH for read cycle.
- 11. Address valid prior to or coincident with \overline{CE} transition LOW.

Notes

- 12. Data I/O is high impedance if $\overline{\text{OE}}$ or $\overline{\text{BHE}}$ and/or $\overline{\text{BLE}} = V_{IH}$.
- 13. If $\overline{\text{CE}}$ goes HIGH simultaneously with $\overline{\text{WE}}$ going HIGH, the output remains in a high impedance state.
