

NCV4274, NCV4274A

400 mA 2% and 4% Voltage Regulator Family

Description

The NCV4274 and NCV4274A is a precision micro-power voltage regulator with an output current capability of 400 mA available in the DPAK, D2PAK and SOT-223 packages.

The output voltage is accurate within $\pm 2.0\%$ or $\pm 4.0\%$ depending on the version with a maximum dropout voltage of 0.5 V with an input up to 40 V. Low quiescent current is a feature drawing only 150 μA with a 1 mA load. This part is ideal for automotive and all battery operated microprocessor equipment.

The regulator is protected against reverse battery, short circuit, and thermal overload conditions. The device can withstand load dump transients making it suitable for use in automotive environments.

Features

- 2.5, 3.3 V, 5.0 V, 8.5 V, $\pm 2.0\%$ Output Options
- 2.5, 3.3 V, 5.0 V, $\pm 4.0\%$ Output Options
- Low 150 μA Quiescent Current at 1 mA load current
- 400 mA Output Current Capability
- Fault Protection
 - -42 V Reverse Voltage
 - Short Circuit
 - Thermal Overload
- Very Low Dropout Voltage
- NCV Prefix for Automotive and Other Applications Requiring Unique Site and Control Change Requirements; AEC-Q100 Qualified and PPAP Capable
- These are Pb-Free Devices

APPLICATION DESCRIPTION

Output Regulator

The output is controlled by a precision trimmed reference and error amplifier. The PNP output has saturation control for regulation while the input voltage is low, preventing over saturation. Current limit and voltage monitors complement the regulator design to give safe operating signals to the processor and control circuits.

Stability Considerations

The input capacitor C_{I1} in Figure 2 is necessary for compensating input line reactance. Possible oscillations caused by input inductance and input capacitance can be damped by using a resistor of approximately $1\ \Omega$ in series with C_{I2} .

The output or compensation capacitor helps determine three main characteristics of a linear regulator: startup delay, load transient response and loop stability.

The capacitor value and type should be based on cost, availability, size and temperature constraints. The aluminum electrolytic capacitor is the least expensive solution, but, if the circuit operates at low temperatures (-25°C to -40°C), both the value and ESR of the capacitor will vary considerably. The capacitor manufacturer's data sheet usually provides this information.

The value for the output capacitor C_O shown in Figure 2 should work for most applications; however, it is not necessarily the optimized solution. Stability is guaranteed at values $C_O \geq 2.2\ \mu\text{F}$ and an $\text{ESR} \leq 2.5\ \Omega$ within the operating temperature range. Actual limits are shown in a graph in the Typical Performance Characteristics section.

Calculating Power Dissipation in a Single Output Linear Regulator

The maximum power dissipation for a single output regulator (Figure 3) is:

$$P_{D(\text{max})} = [V_{I(\text{max})} - V_{Q(\text{min})}]I_{Q(\text{max})} + V_{I(\text{max})}I_q \quad (\text{eq. 1})$$

Where:

$V_{I(\text{max})}$ is the maximum input voltage,

$V_{Q(\text{min})}$ is the minimum output voltage,

$I_{Q(\text{max})}$ is the maximum output current for the application, and

I_q is the quiescent current the regulator consumes at $I_{Q(\text{max})}$.

Once the value of $P_{D(\text{max})}$ is known, the maximum permissible value of $R_{\theta JA}$ can be calculated:

$$P_{\theta JA} = \frac{(150^{\circ}\text{C} - T_A)}{P_D} \quad (\text{eq. 2})$$

The value of $R_{\theta JA}$ can then be compared with those in the package section of the data sheet. Those packages with $R_{\theta JA}$'s less than the calculated value in Equation 2 will keep the die temperature below 150°C . In some cases, none of the packages will be sufficient to dissipate the heat generated by the IC, and an external heat sink will be required. The current flow and voltages are shown in the Measurement Circuit Diagram.

Heat Sinks

A heat sink effectively increases the surface area of the package to improve the flow of heat away from the IC and into the surrounding air.

Each material in the heat flow path between the IC and the outside environment will have a thermal resistance. Like series electrical resistances, these resistances are summed to determine the value of $R_{\theta JA}$:

$$R_{\theta JA} = R_{\theta JC} + R_{\theta CS} + R_{\theta SA} \quad (\text{eq. 3})$$

Where:

$R_{\theta JC}$ = the junction-to-case thermal resistance,

$R_{\theta CS}$ = the case-to-heat sink thermal resistance, and

$R_{\theta SA}$ = the heat sink-to-ambient thermal resistance.

$R_{\theta JC}$ appears in the package section of the data sheet.

Like $R_{\theta JA}$, it too is a function of package type. $R_{\theta CS}$ and $R_{\theta SA}$ are functions of the package type, heat sink and the interface between them. These values appear in data sheets of heat sink manufacturers. Thermal, mounting, and heat sinking are discussed in the ON Semiconductor application note AN1040/D, available on the ON Semiconductor Website.
