Altera SDK for OpenCL Programming Guide

1

2014.12.15

OCL002-14.1.0

The Altera SDK for OpenCL Programming Guide provides descriptions, recommendations and usage information on the Altera[®] Software Development Kit (SDK) for OpenCL[™] (AOCL) compiler and tools. The $AOCL^{(1)}$ is an OpenCL⁽²⁾-based heterogeneous parallel programming environment for Altera FPGAs.

AOCL Programming Guide Prerequisites

The *Altera SDK for OpenCL Programming Guide* assumes that you are knowledgeable in OpenCL concepts and application programming interfaces (APIs). It also assumes that you have experience creating OpenCL applications and are familiar with the OpenCL Specification version 1.0.

Before using the Altera Software Development Kit (SDK) for OpenCL (AOCL) or the Altera Runtime Environment (RTE) for OpenCL to program a non-SoC, familiarize yourself with the respective getting started guides. This document assumes that you have performed the following tasks:

- For the AOCL:
 - Download and install the Quartus® II software
 - Download and install the relevant device support
 - Download and install the AOCL
- For the RTE:
 - Download and install the RTE
- Install your FPGA board
- Program your non-SoC device with the hello_world example OpenCL application

If you have not performed the tasks described above, refer to the *Altera SDK for OpenCL Getting Started Guide* or the *Altera RTE for OpenCL Getting Started Guide* for more information.

ISO 9001:2008 Registered

⁽¹⁾ The Altera SDK for OpenCL is based on a published Khronos Specification, and has passed the Khronos Conformance Testing Process. Current conformance status can be found at www.khronos.org/conformance.

⁽²⁾ OpenCL and the OpenCL logo are trademarks of Apple Inc. used by permission of the Khronos Group™.

^{© 2014} Altera Corporation. All rights reserved. ALTERA, ARRIA, CYCLONE, ENPIRION, MAX, MEGACORE, NIOS, QUARTUS and STRATIX words and logos are trademarks of Altera Corporation and registered in the U.S. Patent and Trademark Office and in other countries. All other words and logos identified as trademarks or service marks are the property of their respective holders as described at www.altera.com/common/legal.html. Altera warrants performance of its semiconductor products to current specifications in accordance with Altera's standard warranty, but reserves the right to make changes to any products and services at any time without notice. Altera assumes no responsibility or liability arising out of the application or use of any information, product, or service described herein except as expressly agreed to in writing by Altera. Altera customers are advised to obtain the latest version of device specifications before relying on any published information and before placing orders for products or services.

AOCL FPGA Programming Flow

Before using the AOCL or the RTE to program a Cyclone[®] V SoC Development Kit, familiarize yourself with the respective getting started guides. This document assumes that you have performed the following tasks:

- For the AOCL:
 - Download and install the Quartus II software
 - Download and install the Cyclone V and Stratix® V device support files
 - Download and install the AOCL
- For the RTE:
 - Download and install the RTE
- Install and set up your Cyclone V SoC Development Kit
- Program your SoC with the hello_world example OpenCL application

If you have not performed the tasks described above, refer to the *Altera SDK for OpenCL Cyclone V SoC Getting Started Guide* or the *Altera RTE for OpenCL Getting Started Guide* for more information.

AOCL FPGA Programming Flow

The Altera Software Development Kit (SDK) for OpenCL (AOCL) programs an FPGA with an OpenCL application in a two-step process. The Altera Offline Compiler (AOC) first compiles your OpenCL kernels. The host-side C compiler compiles your host application and then links the compiled OpenCL kernels to it.

The following figure depicts the AOCL FPGA programming flow:

Figure 1-1: The AOCL FPGA Programming Flow

Before you compile your OpenCL kernels, you must consolidate your kernel source files into a single .cl source file. The OpenCL kernel source file (.cl) contains your OpenCL source code. The AOC compiles your kernel and generates the following files and folders:

- The Altera Offline Compiler Object file (.aoco) is an intermediate object file that contains information for later stages of the compilation.
- The *Altera Offline Compiler Executable file* (.aocx) is the hardware configuration file and contains information necessary at runtime.
- The

The AOC creates the .aocx file from the contents of the your_kernel_filename> folder or subdirectory. It
also incorporates information from the .aoco file into the .aocx file during hardware compilation. The .aocx
file contains data that the host application uses to create program objects for the target FPGA. The host
application loads these program objects into memory. The host runtime then calls these program objects
from memory and programs the target FPGA as required.

AOC Kernel Compilation Flows

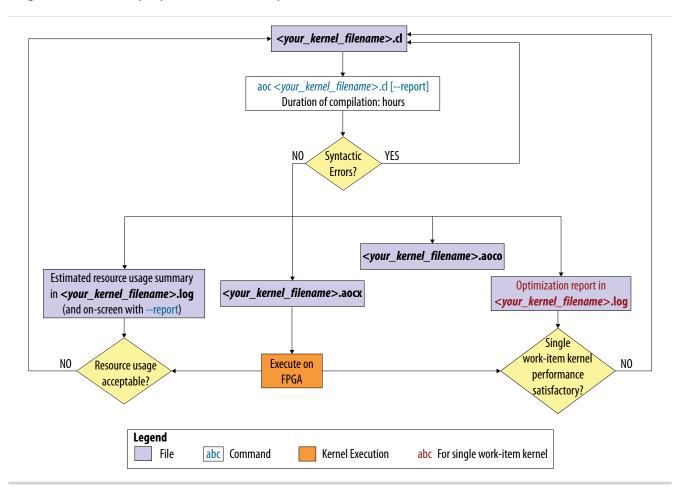

The Altera Offline Compiler (AOC) can create your FPGA hardware configuration file in a one-step or a multistep process. The complexity of your kernel dictates the AOC compilation option you implement.

One-Step Compilation for Simple Kernels

By default, the AOC compiles your OpenCL kernel and creates the hardware configuration file in a single step. Choose this compilation option only if your OpenCL application requires minimal optimizations.

The following figure illustrates the OpenCL kernel design flow that has a single compilation step.

Figure 1-2: One-Step OpenCL Kernel Compilation Flow

A successful compilation results in the following files and reports:

- Altera Offline Compiler Object file (.aoco)
- Altera Offline Compiler Executable file (.aocx)
- In the

 filename > log file, the estimated resource usage summary provides a preliminary assessment of area usage. If you have a single work-item kernel, the optimization report identifies performance bottlenecks.

Attention: It is very time consuming to iterate on your design using the one-step compilation flow. For each iteration, you must perform a full compilation, which takes hours. Then you must execute the kernel on the FPGA before you can assess its performance.

Related Information

Compiling Your Kernel to Create Hardware Configuration File on page 1-57

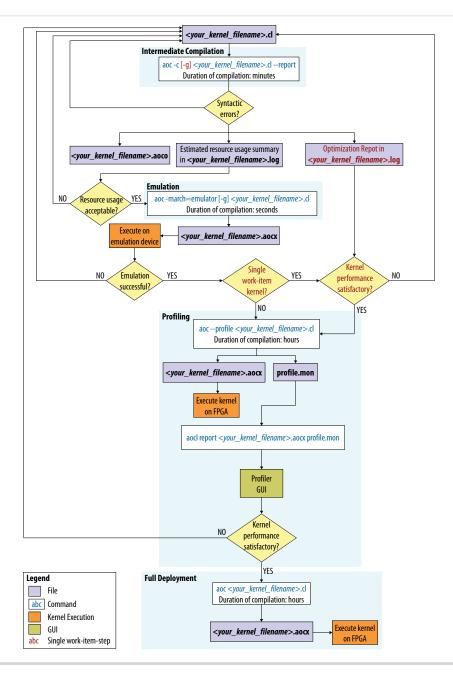

Multistep AOCL Design Flow

Choose the multistep Altera Software Development Kit (SDK) for OpenCL (AOCL) design flow if you want to iterate on your OpenCL kernel design to implement performance-improving optimizations .

The figure below outlines the stages in the AOCL design flow. The steps in the design flow serve as checkpoints for identifying functional errors and performance bottlenecks. They allow you to modify your OpenCL kernel code without performing a full compilation after each iteration.

Figure 1-3: The Multistep AOCL Design Flow

The AOCL design flow includes the following steps:

1. Intermediate compilation

The intermediate compilation step checks for syntatic errors. It then generates an Altera Offline Compiler Object file (.aoco) without building the hardware configuration file. The estimated resource usage summary in the <your_kernel_filename>/<your_kernel_filename>log file can provide insight into the

type of kernel optimizations you can perform. For a single work-item kernel, include the -g option to insert source information in the optimization report in the **<your_kernel_filename>.log** file.

2. Emulation

Assess the functionality of your OpenCL kernel by executing it on one or multiple emulation devices on an x86-64 host. For Linux systems, include the –g option to enable symbolic debug support. Symbolic debug allows you to locate the origins of functional errors in your kernel code.

3. Profiling

Instruct the AOC to instrument performance counters in the Verilog code in the Altera Offline Compiler Executable file (.aocx). During execution, the performance counters collect performance information which you can then review in the profiler GUI.

4. Full deployment

If you are satisfied with the performance of your OpenCL kernel throughout the design flow, perform a full compilation. You can then execute the .aocx file on the FPGA.

Obtaining General Information on Software, Compiler, and Custom Platform

The Altera Software Development Kit (SDK) for OpenCL (AOCL) includes two sets of command options: the AOCL utility commands (aocl <command_option>) and the Altera Offline Compiler (AOC) commands (aoc <command_option>). Each set of commands includes options you can invoke to obtain general information on the software, the compiler, and the Custom Platform.

Displaying the Software Version (version) on page 1-8

To display the version of the Altera Software Development Kit (SDK) for OpenCL (AOCL), invoke the version utility command.

Displaying the Compiler Version (--version) on page 1-8

To display the version of the Altera Offline Compiler (AOC), invoke the version compiler command.

Listing the AOCL Utility Command Options (help) on page 1-8

To display information on the Altera Software Development Kit (SDK) for OpenCL (AOCL) utility command options, invoke the help utility command.

Listing the AOC Command Options (-h or --help) on page 1-8

To display information on the Altera Offline Compiler (AOC) command options, invoke the help or h compiler command.

Listing the Available FPGA Boards in Your Custom Platform (--list-boards) on page 1-9

To list the FPGA boards available in your Custom Platform, include the --list-boards option in the aoc command.

Send Feedback

Displaying the Software Version (version)

To display the version of the Altera Software Development Kit (SDK) for OpenCL (AOCL), invoke the version utility command.

• At the command prompt, invoke the aocl version command. Example output:

```
aocl <version>.<build> (Altera SDK for OpenCL, Version <version>
Build <build>, Copyright (C) 2014 Altera Corporation)
```

Displaying the Compiler Version (--version)

To display the version of the Altera Offline Compiler (AOC), invoke the version compiler command.

• At a command prompt, invoke the aoc --version command. Example output:

Listing the AOCL Utility Command Options (help)

To display information on the Altera Software Development Kit (SDK) for OpenCL (AOCL) utility command options, invoke the help utility command.

At a command prompt, invoke the aocl help command.
 The AOCL categorizes the utility command options based on their functions. It also provides a description for each option.

Displaying Information on an AOCL Utility Command Option (help <command_option>)

To display information on a specific Altera Software Development Kit (SDK) for OpenCL (AOCL) utility command option, include the subcommand as an argument of the help utility command.

• At a command prompt, invoke the aocl help <command_option> command. For example, to obtain more information on the install utility command option, invoke the aocl help install command.

Example output:

```
aocl install - Installs a board onto your host system.

Usage: aocl install

Description:
This command installs a board's drivers and other necessary software for the host operating system to communicate with the board.

For example this might install PCIe drivers.
```

Listing the AOC Command Options (-h or --help)

To display information on the Altera Offline Compiler (AOC) command options, invoke the help or h compiler command.

• At a command prompt, invoke the aoc --help or aoc -h command.

The Altera Software Development Kit (SDK) for OpenCL (AOCL) categorizes the AOC command options based on their functions. It also provides a description for each option.

Listing the Available FPGA Boards in Your Custom Platform (--list-boards)

To list the FPGA boards available in your Custom Platform, include the --list-boards option in the aoc command.

Before you begin

To view the list of available boards in your Custom Platform, you must first set the environment variable *AOCL_BOARD_PACKAGE_ROOT* to point to the location of your Custom Platform.

At a command prompt, invoke the aoc --list-boards command.
 The Altera Offline Compiler (AOC) generates an output that resembles the following:

where *<board_name_N>* is the board name you use in your aoc command to target a specific FPGA board.

Managing an FPGA Board

The Altera Software Development Kit (SDK) for OpenCL (AOCL) includes utility commands you can invoke to install, uninstall, diagnose, and program your FPGA board.

Installing an FPGA Board (install) on page 1-10

To target an FPGA board, you must first download and install the Custom Platform from your board vendor.

Uninstalling the FPGA Board (uninstall) on page 1-11

To uninstall an FPGA board, invoke the uninstall utility command, uninstall the Custom Platform, and unset the relevant environment variables.

Querying the Device Name of Your FPGA Board (diagnose) on page 1-11

When you query a list of accelerator boards, the software produces a list of installed devices on your machine in the order of their device names.

Running a Board Diagnostic Test (diagnose <device_name>) on page 1-12

To perform a detailed diagnosis on a specific FPGA board, include *device_name* as an argument of the diagnose utility command.

Programming the FPGA Offline or without a Host (program <device_name>) on page 1-12

To program an FPGA device offline or without a host, invoke the program utility command.

Programming the Flash Memory (flash <device_name>) on page 1-12

If supported, invoke the flash utility command to initialize the FPGA with a specified startup configuration.

Installing an FPGA Board (install)

To target an FPGA board, you must first download and install the Custom Platform from your board vendor. Most Custom Platform installers require administrator privileges.

The steps below outline the board installation procedure. Some Custom Platforms require additional installation tasks. Consult your board vendor's documentation for further information on board installation.

Attention: If you are installing the Cyclone V SoC Development Kit for use with the Cyclone V SoC Development Kit Reference Platform, refer to the *Altera SDK for OpenCL Cyclone V SoC Getting Started Guide* for more information.

- 1. Follow your board vendor's instructions to connect the FPGA board to your system.
- **2.** Download the Custom Platform for your FPGA board from your board vendor's website. For more information, refer to the OpenCL Reference Platforms page of the Altera website.
- **3.** Install the Custom Platform to a folder or directory.
- **4.** Set the environment variable *AOCL_BOARD_PACKAGE_ROOT* to the subfolder or subdirectory within the Custom Platform that contains the **board_env.xml** file.
 - For example, for the Stratix V Network Reference Platform (s5_net), set AOCL_BOARD_PACKAGE_ROOT to point to the ref/s5_net/sleet or directory.
- **5.** Add the Custom Platform library paths to the *PATH* (Windows) or *LD_LIBRARY_PATH* (Linux) environment variable. You may apply permanent settings manually or apply transient settings to the current command window by running the **init_opencl** script.
 - **a.** Apply permanent settings by adding the path to the memory-mapped (MMD) library within the Custom Platform.
 - b. Apply transient settings by opening a new command window and running the %ALTERAOCLSDKROOT %\init_opencl.bat (Windows) or \$ALTERAOCLSDKROOT/init_opencl.sh (Linux) script.

For example, if you use s5_net, the Windows *PATH* environment variable setting is **%AOCL_BOARD_PACKAGE_ROOT**%\windows64\bin. The Linux *LD_LIBRARY_PATH* setting is **\$AOCL_BOARD_PACKAGE_ROOT**/linux64/lib.

For more information on the init_opencl script, refer to the Setting the Environment Variables on Windows and Setting the Environment Variables on Linux sections of the Altera SDK for OpenCL Getting Started Guide.

- **6.** Invoke the command aocl install at a command prompt.
 - Invoking the aocl install command also installs a board driver that allows communication between host applications and hardware kernel programs.
- 7. To query a list of FPGA devices installed in your machine, invoke the aocl diagnose command. The software generates an output that includes the *<device_name>*, which is an acl number that ranges from acl0 to acl15.
 - For more information on querying the *<device_name>* of your accelerator board, refer to the *Querying the Device Name of Your FPGA Board* section.
- **8.** To verify the successful installation of the FPGA board, invoke the command aocl diagnose device_name to run any board vendor-recommended diagnostic test.

Related Information

- Altera SDK for OpenCL Cyclone V SoC Getting Started Guide
- Querying the Device Name of Your FPGA Board (diagnose) on page 1-11

• Altera SDK for OpenCL Getting Started Guide

Uninstalling the FPGA Board (uninstall)

To uninstall an FPGA board, invoke the uninstall utility command, uninstall the Custom Platform, and unset the relevant environment variables. You must uninstall the existing FPGA board if you migrate your OpenCL application to another FPGA board from a different Custom Platform.

To uninstall your FPGA board, perform the following tasks:

- 1. Following your board vendor's instructions to disconnect the board from your machine.
- 2. Invoke the aocl uninstall utility command to remove the current host computer drivers. The Altera Software Development Kit (SDK) for OpenCL (AOCL) uses these drivers to communicate with the FPGA board.

For example, PCI Express® (PCIe®) drivers

- 3. Uninstall the Custom Platform.
- **4.** Unset the environment variable *LD_LIBRARY_PATH* (for Linux) or *PATH* (for Windows).
- **5.** Unset the environment variable *AOCL_BOARD_PACKAGE_ROOT*.

Querying the Device Name of Your FPGA Board (diagnose)

Some Altera Software Development Kit (SDK) for OpenCL utility commands require you to specify the device name (<device_name>). The <device_name> refers to the acl number (e.g. acl0 to acl15) that corresponds to the FPGA device. When you query a list of accelerator boards, the software produces a list of installed devices on your machine in the order of their device names.

To query a list of installed devices on your machine, perform the following task:

Type aocl diagnose at a command prompt.
 The software generates an output that resembles the example shown below:

```
aocl diagnose: Running diagnostic from ALTERAOCLSDKROOT/board/<br/>board_name>/
<platform>/libexec
Verified that the kernel mode driver is installed on the host machine.
Using board package from vendor: <board_vendor_name>
Querying information for all supported devices that are installed on the host
machine ...
device_name Status Information
acl0
             Passed <descriptive_board_name>
                     PCIe dev_id = <device_ID>, bus:slot.func = 02:00.00,
                       at Gen 2 with 8 lanes.
                     FPGA temperature=43.0 degrees C.
acl1
             Passed <descriptive_board_name>
                     PCIe dev_id = <device_ID>, bus:slot.func = 03:00.00,
                       at Gen 2 with 8 lanes.
                     FPGA temperature = 35.0 degrees C.
Found 2 active device(s) installed on the host machine, to perform a full
diagnostic on a specific device, please run aocl diagnose <device_name>
DIAGNOSTIC PASSED
```

Related Information

Probing the OpenCL FPGA Devices on page 1-53

Running a Board Diagnostic Test (diagnose <device_name>)

To perform a detailed diagnosis on a specific FPGA board, include *device_name* as an argument of the diagnose utility command.

• At a command prompt, invoke the aocl diagnose *<device_name>* command, where *<device_name>* is the acl number (for example, acl0 to acl15) that corresponds to your FPGA device. You can identify the *<device_name>* when you query the list of installed boards in your system.

Consult your board vendor's documentation for more board-specific information on using the diagnose utility command to run diagnostic tests on multiple FPGA boards.

Programming the FPGA Offline or without a Host (program <device_name>)

To program an FPGA device offline or without a host, invoke the program utility command.

At a command prompt, invoke the aocl program <device_name>
 <your_kernel_filename>.aocx command
 where:

<device_name> refers to the acl number (for example, acl0 to acl15) that corresponds to your FPGA device, and

<your_kernel_filename>.aocx is the Altera Offline Compiler Executable file you use to program the
hardware.

Programming the Flash Memory (flash <device_name>)

If supported, invoke the flash utility command to initialize the FPGA with a specified startup configuration.

Note: For instructions on programming the SD flash card of the Cyclone V SoC Development Kit, refer to the *Altera SDK for OpenCL Cyclone V SoC Getting Started Guide*.

At a command prompt, invoke the aocl flash <device_name>
<your_kernel_filename>.aocx command
where:

<device_name> refers to the acl number (for example, acl0 to acl15) that corresponds to your FPGA
device, and

<your_kernel_filename>.aocx is the Altera Offline Compiler Executable file you use to program the
hardware.

Structuring Your OpenCL Kernel

Altera offers recommendations on how to structure your OpenCL kernel code. Consider implementing these programming recommendations when you create a kernel or modify a kernel written originally to target another architecture.

Guidelines for Naming the Kernel on page 1-13

Altera recommends that you include only alphanumeric characters in your filenames.

Programming Strategies for Optimizing Data Processing Efficiency on page 1-14

Optimize the data processing efficiency of your kernel by implementing strategies such as unrolling loops, setting work-group sizes, and specifying compute units and work-items.

Programming Strategies for Optimizing Memory Access Efficiency on page 1-16

Optimize the memory access efficiency of your kernel by implementing strategies such as specifying local memory pointer size and specifying global memory buffer location.

Implementing AOCL Channels Extension on page 1-17

The Altera Software Development Kit (SDK) for OpenCL (AOCL) channels extension provides a mechanism for passing data to kernels and synchronizing kernels with high efficiency and low latency.

Using Predefined Preprocessor Macros in Conditional Compilation on page 1-34

You may take advantage of predefined preprocessor macros that allow you to conditionally compile portions of your kernel code.

Declaring __constant Address Space Qualifiers on page 1-34

There are several limitations and workarounds you must consider when you include __constant address space qualifiers in your kernel.

Including Structure Data Types as Arguments in OpenCL Kernels on page 1-36

Convert each structure parameter (struct) to a pointer that points to a structure.

Inferring a Register on page 1-39

In general, the AOC chooses registers if the access to a variable is fixed and does not require any dynamic indexes.

Guidelines for Naming the Kernel

Altera recommends that you include only alphanumeric characters in your filenames.

1. Begin a filename with an alphanumeric character.

If the filename of your OpenCL application begins with a nonalphanumeric character, compilation fails with the following error message:

```
Error: Quartus compilation FAILED See quartus_sh_compile.log for the output log.
```

2. Do not differentiate filenames using nonalphanumeric characters.

The Altera Offline Compiler (AOC) translates any nonalphanumeric character into an underscore ("_"). If you differentiate two filenames by ending them with different nonalphanumeric characters only (for example, myKernel#.cl and myKernel&.cl), the AOC translates both filenames to myKernel_.cl.

3. For Windows system, ensure that the combined length of the kernel filename and its file path does not exceed 260 characters.

64-bit Windows 7 has a 260-character limit on the length of a file path. If the combined length of the kernel filename and its file path exceeds 260 characters, the AOC to generate the following error message:

```
The filename or extension is too long. The system cannot find the path specified.
```

In addition to the AOC error message, the following error message appears in the <your_kernel_filename>/quartus_sh_compile.log file:

```
Error: Can't copy <file_type> files: Can't open
<your_kernel_filename> for write: No such file or directory
```

Programming Strategies for Optimizing Data Processing Efficiency

Optimize the data processing efficiency of your kernel by implementing strategies such as unrolling loops, setting work-group sizes, and specifying compute units and work-items.

Unrolling a Loop

The Altera Offline Compiler (AOC) might unroll simple loops even if they are not annotated by a pragma. To direct the AOC to unroll a loop, insert an unroll kernel pragma in the kernel code preceding a loop you wish to unroll.

Attention:

• Provide an unroll factor whenever possible. To specify an unroll factor *N*, insert the #pragma unroll <*N*> directive before a loop in your kernel code.

The AOC attempts to unroll the loop at most $\langle N \rangle$ times.

Consider the code fragment below. By assigning a value of 2 as an argument to #pragma unroll, you direct the AOC to unroll the loop twice.

```
#pragma unroll 2
for(size_t k = 0; k < 4; k++)
{
    mac += data_in[(gid * 4) + k] * coeff[k];
}</pre>
```

• To unroll a loop fully, you may omit the unroll factor by simply inserting the #pragma unroll directive before a loop in your kernel code.

The AOC attempts to unroll the loop fully if it understands the trip count. The AOC issues a warning if it cannot execute the unroll request.

Specifying Work-Group Sizes

Specify a maximum or required work-group size whenever possible. The Altera Offline Compiler (AOC) relies on this specification to optimize hardware usage of the OpenCL kernel without involving excess logic.

If you do not specify a max_work_group_size or a reqd_work_group_size attribute in your kernel, the work-group size assumes a default value depending on compilation time and runtime constraints.

- If your kernel contains a barrier, the AOC sets a default maximum work-group size of 256 work-items.
- If your kernel contains a barrier or refers to the local work-item ID, or if you query the work-group size in your host code, the runtime defaults the work-group size to one work-item.
- If your kernel does not contain a barrier or refer to the local work-item ID, or if your host code does not query the work-group size, the runtime defaults the work-group size to the global NDRange size.

To specify the work-group size, modify your kernel code in the following manner:

• To specify the maximum number of work-items the AOC may allocate to a work-group in a kernel, insert the max_work_group_size(X, Y, Z) attribute in your kernel source code. For example:

• To specify the required number of work-items the AOC allocates to a work-group in a kernel, insert the reqd_work_group_size(X, Y, Z) attribute to your kernel source code. For example:

The AOC allocates the exact amount of hardware resources to manage the work-items in a work-group.

Specifying Number of Compute Units

To increase the data-processing efficiency of an OpenCL kernel, you can instruct the Altera Offline Compiler (AOC) to generate multiple kernel compute units, each capable of executing multiple workgroups simultaneously.

Caution: Multiplying the number of kernel compute units increases data throughput at the expense of global memory bandwidth contention among compute units.

• To specify the number of compute units for a kernel, insert the $num_compute_units(N)$ attribute in the kernel source code.

For example, the code fragment below directs the AOC to instantiate two compute units in a kernel:

The AOC distributes work-groups across the specified number of compute units.

Specifying Number of SIMD Work-Items

To increase the data-processing efficiency of an OpenCL kernel, specify the number of work-items within a work-group that the Altera Offline Compiler (AOC) executes in a single instruction multiple data (SIMD) manner.

Important: Introduce the num_simd_work_items attribute in conjunction with the reqd_work_group_size attribute. The num_simd_work_items attribute you specify must evenly divides the work-group size you specify for the reqd_work_group_size attribute.

• To specify the number of SIMD work-items in a work-group, insert the num_simd_work_item(*N*) attribute in the kernel source code.

For example, the code fragment below assigns a fixed work-group size of 64 work-items to a kernel. It then consolidates the work-items within each work-group into four SIMD vector lanes:

The AOC replicates the kernel datapath according to the value you specify for num_simd_work_items whenever possible.

Programming Strategies for Optimizing Memory Access Efficiency

Optimize the memory access efficiency of your kernel by implementing strategies such as specifying local memory pointer size and specifying global memory buffer location.

Specifying Pointer Size in Local Memory

Optimize local memory hardware footprint (that is, size) by specifying a pointer size in bytes.

• To specify a pointer size other than the default size of 16 kilobytes (kB), include the local_mem_size(N) attribute in the pointer declaration within your kernel source code. For example:

```
__kernel void myLocalMemoryPointer(
    __local float * A,
    __attribute__((local_mem_size(1024))) __local float * B,
    __attribute__((local_mem_size(32768))) __local float * C)
{
    //statements
}
```

In the myLocalMemoryPointer kernel, 16 kB of local memory (default) is allocated to pointer A, 1 kB is allocated to pointer B, and 32 kB is allocated to pointer C.

Specifying Buffer Location in Global Memory

Specify the global memory type to which the host allocates a buffer.

1. Determine the names of the global memory types available on your FPGA board in the following manners:

- Refer to the board vendor's documentation for more information.
- Find the names in the **board_spec.xml** file of your board Custom Platform. For each global memory type, the name is the unique string assigned to the name attribute of the global_mem element.
- 2. To instruct the host to allocate a buffer to a specific global memory type, insert the buffer_location("<memory_type>") attribute, where <memory_type> is the name of the global memory type provided by your board vendor. For example:

If you do not specify the buffer_location attribute, the host allocates the buffer to the default memory type automatically. To determine the default memory type, consult the documentation provided by your board vendor. Alternatively, in the **board_spec.xml** file of your Custom Platform, search for the memory type that is defined first or has the attribute default=1 assigned to it.

Altera recommends that you define the buffer_location attribute in a preprocessor macro for ease of reuse, as shown below:

```
#define QDR\
    __global\
    __attribute__((buffer_location("QDR")))

#define DDR\
    __global\
    __attribute__((buffer_location("DDR")))

_kernel void foo (QDR uint * data, DDR uint * lup)
{
    //statements
}
```

Attention: If you assign a kernel argument to a non-default memory (for example, QDR uint * data and DDR uint * lup from the code above), you cannot declare that argument using the const keyword. In addition, you cannot perform atomic operations with pointers derived from that argument.

Implementing AOCL Channels Extension

The Altera Software Development Kit (SDK) for OpenCL (AOCL) channels extension provides a mechanism for passing data to kernels and synchronizing kernels with high efficiency and low latency.

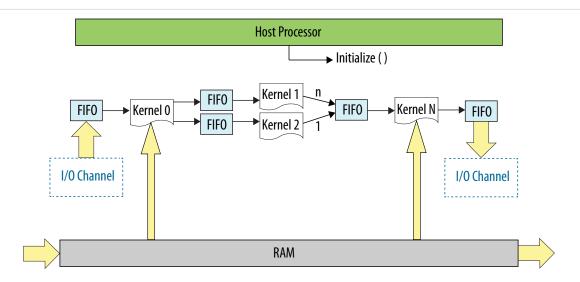

Overview of the AOCL Channels Extension

The Altera Software Development Kit (SDK) for OpenCL (AOCL) channels extension allows kernels to communicate directly with each other via FIFO buffers.

Implementation of channels decouples kernel execution from the host processor. Unlike the typical OpenCL execution model, the host does not need to coordinate data movement across kernels.

The following figure provides an overview of the implementation of channels.

Figure 1-4: AOCL Channels Example

Channel Data Behavior

Data written to a channel remains in a channel as long as the kernel program remains loaded on the FPGA device. In other words, data written to a channel persists across multiple work-groups and NDRange invocations. However, data is not persistent across multiple or different invocations of kernel programs.

Consider the following code example:

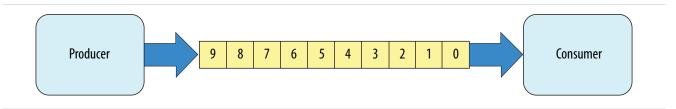

```
#pragma OPENCL EXTENSION cl_altera_channels : enable
channel int c0;

__kernel void producer()
{
   for(int i=0; i < 10; i++)
      {
       write_channel_altera(c0, i);
      }
}

__kernel void consumer( __global uint * restrict dst )
{
   for(int i=0; i < 5; i++)
      {
       dst[i] = read_channel_altera(c0);
      }
}</pre>
```

The figure below illustrates the order in which the producer writes the elements to the channel:

Figure 1-5: Channel Data FIFO Ordering

The kernel producer writes ten elements ([0, 9]). The kernel consumer reads five elements from the channel per NDRange invocation. During the first invocation, the kernel consumer reads values 0 to 4 from the channel. Because the data persists across NDRange invocations, the second time you execute the kernel consumer, it reads values 5 to 9.

For this example, to avoid a deadlock from occurring, you need to invoke the kernel consumer twice for every invocation of the kernel producer. If you call consumer less than twice, producer stalls because the channel becomes full. If you call consumer more than twice, consumer stalls because there is insufficient data in the channel.

Multiple Work-Item Ordering

The OpenCL specification does not define a work-item ordering. The Altera Software Development Kit (SDK) for OpenCL (AOCL) enforces a work-item order to maintain the consistency in channel read and write operations.

Multiple work-item accesses to a channel can be useful in some scenarios. For example, they are useful when data words in the channel are independent, or when the channel is implemented for control logic. The main concern regarding multiple work-item accesses to a channel is the order in which the kernel writes data to and reads data from the channel. If possible, the AOCL channels extension processes work-items read and write operations to the channel in a deterministic order. As such, the read and write operations remain consistent across kernel invocations.

Requirements for Deterministic Multiple Work-Item Ordering

To guarantee deterministic ordering, the AOCL checks that the channel call is work-item invariant based on the following characteristics:

- 1. Work-items must pass through a channel call before exiting the kernel function.
- 2. Work-items must pass through a channel call before entering the ensuing kernel function.
- **3.** If either of the preceding characteristics is not satisfied, the AOCL checks that all branch conditions to the channel call basic block is work-item invariant.

If the AOCL cannot guarantee deterministic ordering of multiple work-item accesses to a channel, it warns you that the channels might not have well-defined ordering with nondeterministic execution. Primarily, the AOCL fails to provide deterministic ordering if you have work-item-variant code on loop executions with channel calls, as illustrated below:

Altera SDK for OpenCL Programming Guide

Altera Corporation

```
{
    for(int i=0; i < N, i++)
    {
        process(data);
        write_channel_altera(req, data[i]);
    }
} else
    {
        process(data);
    }
}</pre>
```

Because the Altera Offline Compiler (AOC) performs many transformations, such as branch conversion, during kernel invocations, it might be difficult to determine if the requirements are fulfilled for a given channel call. The AOCL generates a graphical report on channel connectivity across multiple kernels.

Work-Item Serial Execution

Work-item serial execution refers to an ordered execution behavior where work-item sequential IDs determine their execution order in the compute unit.

When you implement channels in a kernel, the Altera Offline Compiler (AOC) enforces that kernel behavior is equivalent to having at most one work-group in flight. The AOC also ensures that the kernel executes channels in work-item serial execution, where the kernel executes work-items with smaller IDs first. A work-item has the identifier (x, y, z, group), where (x, y, z) is the local 3D identifier, and group is the work-group identifier.

The work-item ID (x0, y0, z0, group0) is considered to be smaller than the ID (x1, y1, z1, group1) if one of the following conditions is true:

- group0 < group1
- group0 = group1 and z0 < z1
- group0 = group1 and z0 = z1 and y0 < y1
- group0 = group1 and z0 = z1 and y0 = y1 and x0 < x1

For example, the work-item with an ID (x0, y0, z0, group0) executes the write channel call first, and then the work-item with an ID (x1, y0, z0, group0) executes the call, and so on, in a sequential order. Defining this order ensures that the system is verifiable with external models.

Channel Execution in Loop with Multiple Work-Items

When channels exist in the body of a loop with multiple work-items, as shown below, each loop iteration executes prior to subsequent iterations. This implies that loop iteration 0 of each work-item in a work-group executes before iteration 1 of each work-item in a work-group, and so on.

```
__kernel void ordering( __global int * data )
{
    write_channel_altera(req, data[get_global_id(0)]);
}
```

AOCL Channels Extension: Restrictions

There are certain design restrictions to the implementation of channels in your OpenCL application.

Single Call Site

Because the channel read and write operations do not function deterministically, for a given kernel, you can only assign one call site per channel ID. For example, the Altera Offline Compiler (AOC) cannot compile the following code example:

```
in_data1 = read_channel_altera(channel1);
in_data2 = read_channel_altera(channel2);
in_data3 = read_channel_altera(channel1);
```

The second read_channel_altera call to channel1 causes compilation failure because it creates a second call site to channel1.

To gather multiple data from a given channel, divide the channel into multiple channels, as shown below:

```
in_data1 = read_channel_altera(channel1);
in_data2 = read_channel_altera(channel2);
in_data3 = read_channel_altera(channel3);
```

Because you can only assign a single call site per channel ID, you cannot unroll loops containing channels. Consider the following code:

```
#pragma unroll 4
for (int i=0; i < 4; i++)
{
    in_data = read_channel_altera(channel1);
}</pre>
```

The AOC issues the following warning message during compilation:

Compiler Warning: Unroll is required but the loop cannot be unrolled.

Feedback and Feed-Forward Channels

Channels within a kernel can be either read_only or write_only. Performance of a kernel that reads and writes to the same channel is poor.

Static Indexing

The Altera Software Development Kit (SDK) for OpenCL (AOCL) channels extension does not support dynamic indexing into arrays of channel IDs.

Kernel Vectorization Support

You cannot vectorize kernels that use channels; that is, do not include the num_simd_work_items kernel attribute in your kernel code. Vectorizing a kernel that uses channels creates multiple channel masters and requires arbitration, which the AOCL channels extension does not support.

Instruction-Level Parallelism on read channel altera and write channel altera Calls

If no data dependencies exist between read_channel_altera and write_channel_altera calls, the AOC attempts to execute these instructions in parallel. As a result, the AOC might execute these read_channel_altera and write_channel_altera calls in an order that does not follow the sequence expressed in the OpenCL kernel code.

Send Feedback

Consider the following code sequence:

```
in_data1 = read_channel_altera(channel1);
in_data2 = read_channel_altera(channel2);
in_data3 = read_channel_altera(channel3);
```

Because there are no data dependencies between the read_channel_altera calls, the AOC can execute them in any order.

Enabling the AOCL Channels for OpenCL Kernel

To implement the Altera Software Development Kit (SDK) for OpenCL (AOCL) channels extension, modify your OpenCL kernels to include channels-specific pragma and application programming interface (API) calls.

Channel declarations are unique within a given OpenCL kernel program. Also, channel instances are unique for every OpenCL kernel program device pair. If the runtime loads a single OpenCL kernel program onto multiple devices, each device will have a single copy of the channel. However, these channel copies are independent and do not share data across the devices.

Declaring the OPENCL EXTENSION pragma

To enable the Altera Software Development Kit (SDK) for OpenCL (AOCL) channels extension, declare the OPENCL EXTENSION pragma for channels at the beginning of your kernel source code.

• To enable the AOCL channels extension, include the following line in your kernel source code to declare the OPENCL EXTENSION pragma:

```
#pragma OPENCL EXTENSION cl_altera_channels : enable
```

Declaring the Channel Handle

Use the channel variable to define the connectivity between kernels or between kernels and I/O.

To read from and write to a channel, the kernel must pass the channel variable to each of the corresponding application programming interface (API) call.

- Declare the channel handle as a file scope variable in the kernel source code in the following convention: channel <type> <variable_name>
 For example: channel int c;
- The AOCL channel extension supports simultaneous channel accesses by multiple variables declared in a data structure. Declare a struct data structure for a channel in the following manner:

```
typedef struct type_ {
    int a;
    int b;
} type_t;
channel type_t foo;
```

Implementing Blocking Channel Write Extensions

The write_channel_altera application programming interface (API) call allows you to send data across a channel.

Note: The write channel calls support single-call sites only. For a given channel, only one write channel call to it can exist in the entire kernel program.

• To implement a blocking channel write, include the following write_channel_altera function signature:

```
void write_channel_altera (channel <type> channel_id, const <type> data);
```

Where:

channel_id identifies the buffer to which the channel connects, and it must match the channel_id of the corresponding read channel (read_channel_altera).

data is the data that the channel write operation writes to the channel. Data <type> must match the <type> of the channel_id.

<type> defines a channel data width, which cannot be a constant. Follow the OpenCL conversion rules to ensure that data the kernel writes to a channel is convertible to <type>.

The following code snippet demonstrates the implementation of the write_channel_altera API call:

```
//Enables the channels extension.
#pragma OPENCL EXTENSION cl_altera_channels : enable

//Defines chan, the kernel file-scope channel variable.
channel long chan;

/*Defines the kernel which reads eight bytes (size of long) from global memory, and passes this data to the channel.*/
   __kernel void kernel_write_channel( __global const long * src )
{
   for(int i=0; i < N; i++)
   {
        //Writes the eight bytes to the channel.
        write_channel_altera(chan, src[i]);
   }
}</pre>
```

Caution: When you send data across a write channel using the write_channel_altera API call, keep in mind that if the channel is full (that is, if the FIFO buffer is full of data), your kernel will stall. Use the Altera Software Development Kit (SDK) for OpenCL (AOCL) profiler to check for channel stalls.

Profiling Your OpenCL Kernel on page 1-70

Implementing Nonblocking Channel Write Extensions

Perform nonblocking channel writes to facilitate applications where data write operations might not occur. A nonblocking channel write extension returns a Boolean value that indicates whether data is written to the channel.

Consider a scenario where your application has one data producer with two identical workers. Assume the time each worker takes to process a message varies depending on the contents of the data. In this case,

Send Feedback

there might be situations where one worker is busy while the other is free. A nonblocking write can facilitate work distribution such that both workers are busy.

• To implement a nonblocking channel write, include the following write_channel_nb_altera function signature:

```
bool write_channel_nb_altera(channel <type> channel_id, const <type> data);
```

The following code snippet of the kernel producer facilitates work distribution using the nonblocking channel write extension:

```
#pragma OPENCL EXTENSION cl_altera_channels : enable
channel long worker0, worker1;
    _kernel void producer( __global const long * src )
{
    for(int i=0; i < N; i++)
    {
        bool success = FALSE;
        do
        {
            success = write_channel_nb_altera(worker0, src[i]);
            if(!success)
            {
                 success = write_channel_nb_altera(worker1, src[i]);
            }
            while(!success);
        }
}</pre>
```

Implementing Blocking Channel Read Extensions

The read_channel_altera application programming interface (API) call allows you to receive data across a channel.

Note: The read channel calls support single-call sites only. For a given channel, only one read channel call to it can exist in the entire kernel program.

• To implement a blocking channel read, include the following read_channel_altera function signature:

```
<type> read_channel_altera(channel <type> channel_id);
```

Where:

channel_id identifies the buffer to which the channel connects, and it must match the channel_id of the corresponding write channel (write_channel_altera).

<type> defines a channel data width, which cannot be a constant. Ensure that the variable the kernel assigns to read the channel data is convertible from <type>.

The following code snippet demonstrates the implementation of the read_channel_altera API call:

```
//Enables the channel extension.
#pragma OPENCL EXTENSION cl_altera_channels : enable;

//Defines chan, the kernel file-scope channel variable.
channel long chan;

/*Defines the kernel, which reads eight bytes (size of long) from the
```

```
channel and writes it back to global memory.*/
    kernel void kernel_read_channel( __global long * dst );
{
    for(int i=0; i < N; i++)
    {
        //Reads the eight bytes from the channel.
        dst[i] = read_channel_altera(chan);
    }
}</pre>
```

Caution: If the channel is empty (that is, if the FIFO buffer is empty), you cannot receive data across a read channel using the read_channel_altera API call. Doing so causes your kernel to stall.

Implementing Nonblocking Channel Read Extensions

Perform nonblocking reads to facilitate applications where data is not always available. The nonblocking reads signature is similar to blocking reads. However, it returns an integer value that indicates whether a read operation takes place successfully.

• To implement a blocking channel write, include the following read_channel_nb_altera function signature:

```
<type> read_channel_nb_altera(channel <type> channel_id, bool * valid);
```

The following code snippet demonstrates the use of the nonblocking channel read extension:

```
#pragma OPENCL EXTENSION cl_altera_channels : enable
channel long chan;

__kernel void kernel_read_channel( __global long * dst )
{
    int i=0;
    while(i < N)
    {
        bool valid0, valid1;
        long data0 = read_channel_nb_altera(chan, &valid0);
        long data1 = read_channel_nb_altera(chan, &valid1);
        if (valid0)
        {
            process(data0);
        }
        if (valid1) process(data1);
        {
                process(data1);
        }
    }
}</pre>
```

Implementing I/O Channels Using the io Channels Attribute

Include an io attribute in your channel declaration to declare a special I/O channel to interface with input or output features of an FPGA board.

These features might include network interfaces, PCI Express (PCIe), cameras, or other data capture or processing devices or protocols.

The io("chan_id") attribute specifies the I/O feature of an accelerator board with which a channel interfaces, where chan_id is the name of the I/O interface listed in the **board_spec.xml** file of your Custom Platform.

Because peripheral interface usage might differ for each device type, consult your board vendor's documentation when you implement I/O channels in your kernel program. Your OpenCL kernel code must be compatible with the type of data generated by the peripheral interfaces.

Caution:

- Implicit data dependencies might exist for channels that connect to the board directly and communicate with peripheral devices via I/O channels. These implicit data dependencies might lead to compilation issues because the Altera Offline Compiler (AOC) cannot identify these dependencies.
- External I/O channels communicating with the same peripherals do not obey any sequential ordering. Ensure that the external device does not require sequential ordering because unexpected behavior might occur.
- 1. Consult the **board_spec.xml** file in your Custom Platform to identify the input and output features available on your FPGA board.

For example, a **board_spec.xml** might include the following information on I/O features:

```
<channels>
  <interface name="udp_0" port="udp0_out" type="streamsource" width="256"
    chan_id="eth0_in"/>
  <interface name="udp_0" port="udp0_in" type="streamsink" width="256"
    chan_id="eth0_out"/>
  <interface name="udp_0" port="udp1_out" type="streamsource" width="256"
    chan_id="eth1_in"/>
  <interface name="udp_0" port="udp1_in" type="streamsink" width="256"
    chan_id="eth1_out"/>
  </channels>
```

The width attribute of an interface element specifies the width, in bits, of the data type used by that channel. For the example above, both the uint and float data types are 32 bits wide. Other bigger or vectorized data types must match the appropriate bit width specified in the **board_spec.xml** file.

2. Implement the io channel attribute as demonstrated in the following code example. The io channel attribute names must match those of the I/O channels (chan_id) specified in the **board_spec.xml** file.

```
channel QUDPWord udp_in_IO __attribute__((depth(0)))
                            __attribute__((io("eth0_in")));
channel QUDPWord udp_out_IO __attribute__((depth(0)))
                              _attribute__((io("eth0_out")));
__kernel void io_in_kernel( __global ulong4 *mem_read,
                            uchar read_from,
                            int size )
 int index = 0;
 ulong4 data;
 int half_size = size >> 1;
 while (index < half_size)</pre>
    if (read_from & 0x01)
     data = read_channel_altera(udp_in_IO);
    else
     data = mem_read[index];
    write_channel_altera(udp_in, data);
    index++;
}
__kernel void io_out_kernel( __global ulong2 *mem_write,
```

```
uchar write_to,
                              int size )
  int index = 0;
  ulong4 data;
  int half_size = size >> 1;
  while (index < half_size)</pre>
    ulong4 data = read_channel_altera(udp_out);
    if (write_to & 0x01)
     write_channel_altera(udp_out_IO, data);
    else
      //only write data portion
      ulong2 udp_data;
      udp_data.s0 = data.s0;
      udp_data.s1 = data.s1;
      mem_write[index] = udp_data;
    index++;
}
```

Attention: Declare a unique io("chan_id") handle for each I/O channel specified in the channels eXtensible Markup Language (XML) element within the **board_spec.xml** file.

Implementing Buffered Channels Using the depth Channels Attribute

You may have buffered or unbuffered channels in your kernel program. If there are imbalances in channel read and write operations, create buffered channels to prevent kernel stalls by including the depth attribute in your channel declaration. Buffered channels decouple the operation of concurrent work-items executing in different kernels.

You may use a buffered channel to control data traffic, such as limiting throughput or synchronizing accesses to shared memory. In an unbuffered channel, a write operation cannot proceed until the read operation reads a data value. In a buffered channel, a write operation cannot proceed until the data value

is copied to the buffer. If the buffer is full, the operation cannot proceed until the read operation reads a piece of data and removes it from the channel.

• If you expect any temporary mismatch between the consumption rate and the production rate to the channel, set the buffer size using the depth channel attribute.

The following example demonstrates the use of the depth channel attribute in kernel code that implements the Altera Software Development Kit (SDK) for OpenCL (AOCL) channels extension. The depth(N) attribute specifies the minimum depth of a buffered channel, where N is the number of data values.

In this example, the write operation can write ten data values to the channel without blocking. Once the channel is full, the write operation cannot proceed until an associated read operation to the channel occurs.

Because the channel read and write calls are conditional statements, the channel might experience an imbalance between read and write calls. You may add a buffer capacity to the channel to ensure that the producer and consumer kernels are decoupled. This step is particularly important if the producer kernel is writing data to the channel when the consumer kernel is not reading from it.

Enforcing the Order of Channel Calls

To enforce the order of channel calls, introduce memory fence or barrier functions in your kernel program to control memory accesses. A memory fence function is necessary to create a control flow dependence between the channel synchronization calls before and after the fence.

When the Altera Offline Compiler (AOC) generates a compute unit, it does not create instruction-level parallelism on all instructions that are independent of each other. As a result, channel read and write operations might not execute independently of each other even if there is no control or data dependence between them. When channel calls interact with each other, or when channels write data to external devices, deadlocks might occur.

For example, the code snippet below consists of a producer kernel and a consumer kernel. Channels co and c1 are unbuffered channels. The schedule of the channel read operations from c0 and c1 might occur in the reversed order as the channel write operations to c0 and c1. That is, the producer kernel writes to c0 but the consumer kernel might read from c1 first. This rescheduling of channel calls might cause a deadlock because the consumer kernel is reading from an empty channel.

}

• To prevent deadlocks from occurring by enforcing the order of channel calls, include memory fence functions (mem_fence) in your kernel.

In the kernel code above, by inserting the mem_fence call with the channel flag, you force the sequential ordering of the write and read channel calls in the producer and consumer kernels:

```
#pragma OPENCL EXTENSION cl_altera_channels : enable
channel uint c0 __attribute__((depth(0)));
channel uint c1 __attribute__((depth(0)));
__kernel void producer( __global const uint * src,
                         const uint iterations )
    for(int i=0; i < iterations; i++)</pre>
        write_channel_altera(c0, src[2*i]);
        mem_fence(CLK_CHANNEL_MEM_FENCE);
        write_channel_altera(c1, src[2*i+1]);
}
__kernel void consumer( __global uint * dst;
                        const uint iterations )
    for(int i=0; i < iterations; i++)</pre>
        dst[2*i+1] = read_channel_altera(c0);
        mem_fence(CLK_CHANNEL_MEM_FENCE);
        dst[2*i] = read_channel_altera(c1);
    }
}
```

In this example, mem_fence in the producer kernel ensures that the channel write operation to co occurs before that to c1. Similarly, mem_fence in the consumer kernel ensures that the channel read operation from c0 occurs before that from c1.

Defining Memory Consistency Across Kernels

According to the OpenCL Specification version 1.0, memory behavior is undefined unless a kernel completes execution. A kernel must finish executing before other kernels can visualize any changes in memory behavior. However, kernels that use channels can share data through common global memory buffers and synchronized memory accesses. To ensure that data written to a channel is visible to the read channel after execution passes a memory fence, define memory consistency across kernels with respect to memory fences.

• To create a control flow dependency between the channel synchronization calls and the memory operations, add the CLK_GLOBAL_MEM_FENCE flag to the mem_fence call. For example:

In this kernel, the mem_fence function ensures that the write operation to c0 and memory access to src[2*i] occur before the write operation to c1 and memory access to src[2*i+1]. This allows data written to c0 to be visible to the read channel before data is written to c1.

Use Models of AOCL Channels Implementation

Concurrent execution can improve the effectiveness of channels implementation in your OpenCL kernels. During concurrent execution, the host launches the kernels in parallel. The kernels share memory and can communicate with each other through channels where applicable.

The use models provide an overview on how to exploit concurrent execution safely and efficiently.

Feed-Forward Design Model

Implement the feed-forward design model to send data from one kernel to the next without creating any cycles between them. Consider the following code example:

Altera SDK for OpenCL Programming Guide

The producer kernel writes data to channels c0 and c1. The consumer kernel reads data from c0 and c1. The figure below illustrates the feed-forward data flow between the two kernels:

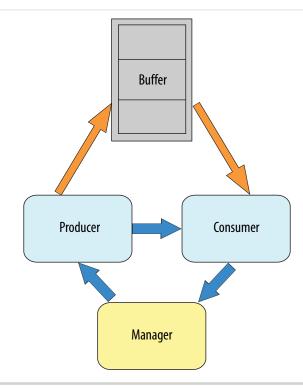

Figure 1-6: Feed-Forward Data Flow

Buffer Management

In the feed-forward design model, data traverses between the producer and consumer kernels one word at a time. To facilitate the transfer of large data messages consisting of several words, you can implement a ping-pong buffer, which is a common design pattern found in applications for communication. The figure below illustrates the interactions between kernels and a ping-pong buffer:

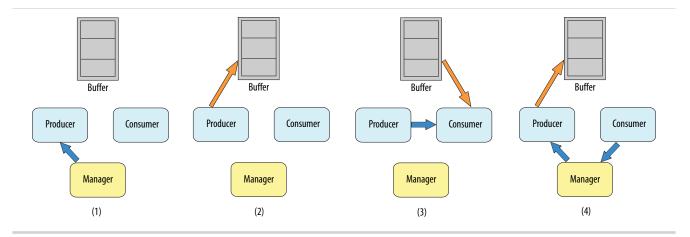

Figure 1-7: Feed-Forward Design Model with Buffer Management

The manager kernel manages circular buffer allocation and deallocation between the producer and consumer kernels. After the consumer kernel processes data, the manager receives memory regions that the consumer frees up and sends them to the producer for reuse. The manager also sends to the producer kernel the initial set of free locations, or tokens, to which the producer can write data.

The following figure illustrates the sequence of events that take place during buffer management:

Figure 1-8: Kernels Interaction during Buffer Management

- 1. The manager kernel sends a set of tokens to the producer kernel to indicate initially which regions in memory are free for producer to use.
- 2. After manager allocates the memory region, producer writes data to that region of the ping-pong buffer.
- 3. After producer completes the write operation, it sends a synchronization token to the consumer kernel to indicate what memory region contains data for processing. The consumer kernel then reads data from that region of the ping-pong buffer.

Note: When consumer is performing the read operation, producer can write to other free memory locations for processing because of the concurrent execution of the producer, consumer, and manager kernels.

4. After consumer completes the read operation, it releases the memory region and sends a token back to the manager kernel. The manager kernel then recycles that region for producer to use.

Implementation of Buffer Management for AOCL Kernels

To ensure that the Altera Software Development Kit (SDK) for OpenCL (AOCL) implements buffer management properly, the ordering of channel read and write operations is important. The synchronization token must occur after the producer kernel commits data to memory. In other words, the channel write operation cannot occur until producer stores its data successfully. To preserve this ordering, include an OpenCL mem_fence token in your kernels, as shown below:

Altera SDK for OpenCL Programming Guide

```
shared_mem[base_offset + lID] = src[gID];

// Make sure all memory operations are committed before
// sending token to the consumer
mem_fence(CLK_GLOBAL_MEM_FENCE | CLK_CHANNEL_MEM_FENCE);

if (lID == 255)
{
    write_channel_altera(c, base_offset);
}
}
```

The mem_fence construct takes two flags: CLK_GLOBAL_MEM_FENCE and CLK_CHANNEL_MEM_FENCE. The mem_fence effectively creates a control flow dependence between operations that occur before and after the mem_fence call. The CLK_GLOBAL_MEM_FENCE flag indicates that global memory operations must obey the control flow. The CLK_CHANNEL_MEM_FENCE indicates that channel operations must obey the control flow. As a result, the write_channel_altera call in the example cannot start until the global memory operation is committed to the shared memory buffer.

Using Predefined Preprocessor Macros in Conditional Compilation

You may take advantage of predefined preprocessor macros that allow you to conditionally compile portions of your kernel code.

• To include device-specific (for example, FPGA_board_1) code in your kernel program, structure your kernel program in the following manner:

When you target your kernel compilation to a specific board, it sets the predefined preprocessor macro AOCL_BOARD_

board_name> to 1. If

board_name> is FPGA_board_1, the Altera Offline Compiler (AOC) will compile the FPGA_board_1-specific parameters and features.

• To introduce AOC-specific compiler features and optimizations, structure your kernel program in the following manner:

```
#if defined(ALTERA_CL)
    //statements
#else
    //statements
#endif
```

Where ALTERA_CL is the Altera predefined preprocessor macro for the AOC.

Related Information

Defining Preprocessor Macros to Specify Kernel Parameters (-D <macro_name>) on page 1-60

Declaring __constant Address Space Qualifiers

There are several limitations and workarounds you must consider when you include __constant address space qualifiers in your kernel.

Function Scope __constant Variables

The Altera Offline Compiler (AOC) does not support function scope __constant variables. Replace function scope __constant variables with file scope constant variables. You can also replace function scope __constant variables with __constant buffers that the host passes to the kernel.

File Scope __constant Variables

If the host always passes the same constant data to your kernel, consider declaring that data as a constant preinitialized file scope array within the kernel file. Declaration of a constant preinitialized file scope array creates a ROM directly in the hardware to store the data. This ROM is available to all work-items in the NDRange.

The AOC supports only scalar file scope constant data. For example, you may set the __constant address space qualifier as follows:

```
__constant int my_array[8] = {0x0, 0x1, 0x2, 0x3, 0x4, 0x5, 0x6, 0x7};
__kernel void my_kernel (__global int * my_buffer)
{
    size_t gid = get_global_id(0);
    my_buffer[gid] += my_array[gid % 8];
}
```

In this case, the AOC sets the values for my_array in a ROM because the file scope constant data does not change between kernel invocations.

Warning: Do not set your file scope __constant variables in the following manner because the AOC does not support vector type __constant arrays declared at the file scope:

```
__constant int2 my_array[4] = \{(0x0, 0x1), (0x2, 0x3); (0x4, 0x5), (0x6, 0x7)\};
```

Pointers to __constant Parameters from the Host

You can replace file scope constant data with a pointer to a __constant parameter in your kernel code. You must then modify your host application in the following manner:

- 1. Create cl_mem memory objects associated with the pointers in global memory.
- 2. Load constant data into cl_mem objects with clenqueueWriteBuffer prior to kernel execution.
- 3. Pass the cl_mem objects to the kernel as arguments with the clSetKernelArg function.

For simplicity, if a constant variable is of a complex type, use a typedef argument, as shown in the table below:

Table 1-1: Replacing File Scope __constant Variable with Pointer to __constant Parameter

If your source code is structured as follows:	Rewrite your code to resemble the following syntax:
<pre>constant int Payoff[2][2] = {{ 1, 3}, {5, 3}}; kernel void original(global int * A) { *A = Payoff[1][2]; // and so on }</pre>	<pre>kernel void modified(global int * A,constant Payoff_type * PayoffPtr) { *A = (PayoffPtr)[1][2]; // and so on }</pre>

Attention: Use the same type definition in both your host application and your kernel.

Including Structure Data Types as Arguments in OpenCL Kernels

Convert each structure parameter (struct) to a pointer that points to a structure.

The table below describes how you can convert structure parameters:

Table 1-2: Converting Structure Parameters to Pointers that Point to Structures

```
If your source code is structured as follows:
                                                Rewrite your code to resemble the following syntax:
struct Context
                                                struct Context
   float param1;
                                                  float param1;
   float param2;
                                                  float param2;
   int param3;
                                                  int param3;
   uint param4;
                                                  uint param4;
};
                                               };
 _kernel void algorithm(__global float
                                                 _kernel void algorithm(__global float
* A,
struct Context c)
                                                 _global struct Context * restrict c)
   if (c.param3)
                                                  if ( c->param3 )
                                                   {
                                                      // Dereference through a
      // statements
                                                      // pointer and so on
                                               }
```

Attention: The __global struct declaration creates a new buffer to store the structure. To prevent pointer aliasing, include a restrict qualifier in the declaration of the pointer to the structure.

Matching Data Layouts of Host and Kernel Structure Data Types

If you use structure data types (struct) as arguments in OpenCL kernels, match the member data types and align the data members between the host application and the kernel code.

To match member data types, use the cl_version of the data type in your host application that corresponds to the data type in the kernel code. The cl_version of the data type is available in the **opencl.h** header file. For example, if you have a data member of type float4 in your kernel code, the corresponding data member you declare in the host application is cl_float4.

Align the structures and align the struct data members between the host and kernel applications. Manage the alignments carefully because of the variability among different host compilers.

For example, if you have float 4 OpenCL data types in the struct, the alignments of these data items must satisfy the OpenCL specification (that is, 16-byte alignment for float4).

The following rules apply when the Altera Offline Compiler (AOC) compiles your OpenCL kernels:

- **1.** Alignment of built-in scalar and vector types follow the rules outlined in Section 6.1.5 of the *OpenCL Specification version 1.0*.
 - The AOC usually aligns a data type based on its size. However, the AOC aligns a value of a three-element vector the same way it aligns a four-element vector.
- **2.** An array has the same alignment as one of its elements.
- 3. A struct (or a union) has the same alignment as the maximum alignment necessary for any of its data members.

Consider the following example:

```
struct my_struct
{
    char data[3];
    float4 f4;
    int index;
};
```

The AOC aligns the struct elements above at 16-byte boundaries because of the float4 data type. As a result, both data and index also have 16-byte alignment boundaries.

- **4.** The AOC does not reorder data members of a struct.
- 5. Normally, the AOC inserts a minimum amount of data structure padding between data members of a struct to satisfy the alignment requirements for each data member.
 - a. In your OpenCL kernel code, you may specify data packing (that is, no insertion of data structure padding) by applying the packed attribute to the struct declaration. If you impose data packing, ensure that the alignment of data members satisfies the OpenCL alignment requirements. The Altera Software Development Kit (SDK) for OpenCL (AOCL) does not enforce these alignment requirements. Ensure that your host compiler respects the kernel attribute and sets the appropriate alignments.
 - **b.** In your OpenCL kernel code, you may specify the amount of data structure padding by applying the aligned(*N*) attribute to a data member, where *N* is the amount of padding. The AOCL does not enforce these alignment requirements. Ensure that your host compiler respects the kernel attribute and sets the appropriate alignments.

For Windows systems, some versions of the Microsoft Visual Studio compiler pack structure data types by default. If you do not want to apply data packing, specify an amount of data structure padding as shown below:

```
struct my_struct
{
    __declspec(align(16)) char data[3];

    /*Note that cl_float4 is the only known float4 definition on the host*/
    __declspec(align(16)) cl_float4 f4;

    __declspec(align(16)) int index;
};
```

Tip: An alternative way of adding data structure padding is to insert dummy struct members of type char or array of char.

Related Information

Modifying Host Program for Structure Parameter Conversion on page 1-45

Disabling Insertion of Data Structure Padding

You may instruct the Altera Offline Compiler (AOC) to disable automatic padding insertion between members of a struct data structure.

Send Feedback

• To disable automatic padding insertion, insert the packed attribute prior to the kernel source code for a struct data structure.

For example:

```
_attribute__((packed))
struct Context
{
    float param1;
    float param2;
    int param3;
    uint param4;
};
    __kernel void algorithm(__global float * restrict A, __global struct Context * restrict c)
{
    if ( c->param3 )
    {
        // Dereference through a pointer and so on
    }
}
```

For more information, refer to the *Align a Struct with or without Padding* section of the *Altera SDK for OpenCL Best Practices Guide*.

Altera SDK for OpenCL Best Practices Guide

Specifying the Alignment of a Struct

You may instruct the Altera Offline Compiler (AOC) to set a specific alignment of a struct data structure.

• To specify the struct alignment, insert the aligned(N) attribute prior to the kernel source code for a struct data structure.

For example:

For more information, refer to the *Align a Struct with or without Padding* section of the *Altera SDK for OpenCL Best Practices Guide*.

OCL002-14.1.0 2014.12.15

Inferring a Register

The Altera Offline Compiler (AOC) can implement data that is in the private address space in registers or in block RAMs. In general, the AOC chooses registers if the access to a variable is fixed and does not require any dynamic indexes. Accessing an array with a variable index usually forces the array into block RAMs. Implementing private data as registers is beneficial for data access that occurs in a single cycle (for example, feedback in a single work-item loop).

The AOC infers private arrays as registers either as single values or in a piecewise fashion. Piecewise implementation results in very efficient hardware; however, the AOC must be able to determine data accesses statically. To facilitate piecewise implementation, hardcode the access points into the array. You can also facilitate register inference by unrolling loops that access the array.

If array accesses are not inferable statically, the AOC might infer the array as registers. However, the AOC limits the size of these arrays to 64 bytes in length for single work-item kernels. There is effectively no size limit for kernels with multiple work-items

Consider the following code example:

```
int array[SIZE];
for (int j = 0; j < N; ++j)
{
    for (int i = 0; i < SIZE - 1; ++i)
    {
        array[i] = array[i + 1];
    }
}</pre>
```

The indexing into <code>array[i]</code> is not inferable statically because the loop is not unrolled. If the size of <code>array[i]</code> is less than or equal to 64 bytes for single work-item kernels, the AOC implements <code>array[i]</code> in block RAMs. If the size of <code>array[i]</code> is greater than 64 bytes, or if the kernel has multiple work-items, the AOC implements the entire array into registers as a single value. In this case, the AOC implements data accesses as nonconstant shifts and masks. With complicated addressing, the AOC implements the array in block RAMs and instantiates specialized hardware for each load or store operation.

Inferring a Shift Register

The shift register design pattern is a very important design pattern for many applications. However, the implementation of a shift register design pattern might seem counterintuitive at first.

Consider the following code example:

```
while(1)
{
    // Fully unrolling the shifting loop produces constant accesses
    #pragma unroll
    for (int j=0; j < SIZE-1; j++)
    {
        shift_reg[j] = shift_reg[j + 1];
    }
    shift_reg[SIZE - 1] = read_channel_altera(in);

    // Using fixed access points of the shift register
    int res = (shift_reg[0] + shift_reg[1]) / 2;

    // 'out' channel will have running average of the input channel
    write_channel_altera(out, res);
}</pre>
```

In each clock cycle, the kernel shifts a new value into the array. By placing this shift register into a block RAM, the Altera Offline Compiler (AOC) can efficiently handle multiple access points into the array. The shift register design pattern is ideal for implementing filters (for example, image filters like a Sobel filter or time-delay filters like a finite impulse response (FIR) filter).

When implementing a shift register in your kernel code, keep in mind the following key points:

- 1. Unroll the shifting loop so that it can access every element of the array.
- **2.** All access points must have constant data accesses. For example, if you write a calculation in nested loops using multiple access points, unroll these loops to establish the constant access points.
- **3.** Initialize all elements of the array to the same value. Alternatively, do not initialize any element. Uninitialized elements have a value of 0.
- **4.** If some accesses to a large array are not inferable statically, they force the AOC to create inefficient hardware. If these accesses are necessary, use __local memory instead of __private memory.
- **5.** Do not shift a large shift register conditionally. The shifting must occur in very loop iteration that contains the shifting code to avoid creating inefficient hardware.

Designing Your Host Application

Altera offers guidelines on host requirements and procedures on structuring the host application. If applicable, implement these design strategies when you create or modify a host application for your OpenCL kernels.

Host Programming Requirements on page 1-41

When designing your OpenCL host application for use with the Altera Software Development Kit (SDK) for OpenCL (AOCL), ensure that the application satisfies the following host programming requirements.

Allocating OpenCL Buffer for Manual Partitioning of Global Memory on page 1-41

Collecting Profile Data During Kernel Execution on page 1-43

In cases where kernel execution finishes after the host application completes, you can query the FPGA explicitly to collect profile data during kernel execution.

Modifying Host Program for Structure Parameter Conversion on page 1-45

If you convert any structure parameters to pointers-to-constant structures in your OpenCL kernel, you must modify your host application accordingly.

Allocating Shared Memory for OpenCL Kernels Targeting SoCs on page 1-45

Altera recommends that OpenCL kernels that run on Altera SoCs access shared memory instead of the FPGA DDR memory.

Managing Host Application on page 1-48

The Altera Software Development Kit (SDK) for OpenCL (AOCL) includes utility commands you can invoke to obtain information on flags and libraries necessary for compiling and linking your host application.

Host Programming Requirements

When designing your OpenCL host application for use with the Altera Software Development Kit (SDK) for OpenCL (AOCL), ensure that the application satisfies the following host programming requirements.

Host Machine Memory Requirements

The machine that runs the host application must have enough host memory to support several components simultaneously.

The host machine must support the following components:

- The host application and operating system.
- The working set for the host application.
- The maximum amount of OpenCL memory buffers that can be allocated at once. Every device-side cl_mem buffer is associated with a corresponding storage area in the host process. Therefore, the amount of host memory necessary might be as large as the amount of external memory supported by the FPGA.

Host Binary Requirement

When compiling the host application, target one of these architectures: x86-64 (64-bit), big-endian (64-bit), or ARM® 32-bit ARMV7-A for devices such as the Cyclone V SoC. The Altera Software Development Kit (SDK) for OpenCL (AOCL) host runtime does not support x86-32 (32-bit) binaries.

Multiple Host Threads

The Altera Software Development Kit (SDK) for OpenCL (AOCL) host library is not thread-safe.

Out-of-Order Command Queues

The OpenCL host runtime command queues do not support out-of-order command execution.

Requirement for Multiple Command Queues in Channels Implementation

Although the Altera Software Development Kit (SDK) for OpenCL (AOCL) channels extension allows multiple kernels to execute in parallel, the AOCL channels facilitate this concurrent behavior only when <code>cl_command_queue</code> objects are in order. To enable multiple command queues , instantiate a separate command for each kernel you wish to run concurrently.

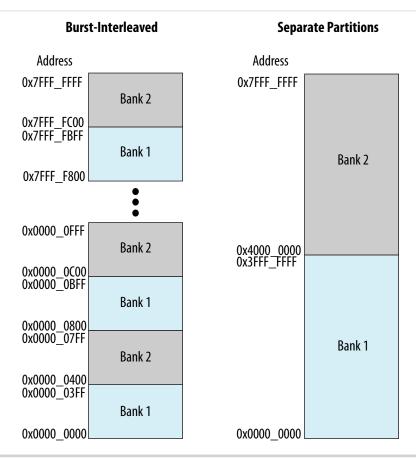

Allocating OpenCL Buffer for Manual Partitioning of Global Memory

Manual partitioning of global memory buffers allows you to control memory accesses across buffers to maximize the memory bandwidth. Before you partition the memory, first you have to disable burst-interleaving during OpenCL kernel compilation. Then, in the host application, you must specify the memory bank to which you allocate the OpenCL buffer.

Send Feedback

By default, the Altera Offline Compiler (AOC) configures each global memory type in a burst-interleaved fashion. Usually, the burst-interleaving configuration leads to the best load balancing between the memory banks. However, there might be situations where it is more efficient to partition the memory into non-interleaved regions.

The figure below illustrates the differences between burst-interleaved and non-interleaved memory partitions.

To manually partition some or all of the available global memory types, perform the following tasks:

- 1. Compile your OpenCL kernel using the --no-interleaving <global_memory_type> flag to configure the memory bank(s) of the specified memory type as separate addresses.
 - For more information on the usage of the --no-interleaving <global_memory_type> flag, refer to the Disabling Burst-Interleaving of Global Memory (--no-interleaving <global_memory_type>) section.
- 2. Create an OpenCL buffer in your host application, and allocate the buffer to one of the banks using the CL_MEM_HETEROGENEOUS_ALTERA and CL_MEM_BANK flags.
 - Specify CL_MEM_BANK_1_ALTERA to allocate the buffer to the lowest available memory region.
 - Specify CL_MEM_BANK_2_ALTERA to allocation memory to the second bank (if available).

Attention: Allocate each buffer to a single memory bank only.

By default, the host allocates buffers into the main memory when you load kernels into the OpenCL runtime via the clcreateProgramWithBinary function. During kernel invocation, the host automati-

cally relocates heterogeneous memory buffers that are bound to kernel arguments to the main memory. To avoid the initial allocation of heterogeneous memory buffers in the main memory, include the CL_MEM_HETEROGENEOUS_ALTERA flag when you call the clcreateBuffer function, as shown below:

For example, the following clcreateBuffer call allocates memory into the lowest available memory region of a nondefault memory bank:

The clCreateBuffer call allocates memory into a certain global memory type based on what you specify in the kernel argument. If a memory (cl_mem) object residing in a memory type is set as a kernel argument that corresponds to a different memory technology, the host moves the memory object automatically when it queues the kernel. Do not pass a buffer as kernel arguments that associate it with multiple memory technologies.

Attention: If the second bank is not available at runtime, the memory is allocated to the first bank. If no global memory is available, the clcreateBuffer call fails with the error message CL MEM OBJECT ALLOCATION FAILURE.

For more information on optimizing heterogeneous global memory accesses, refer to the *Heterogeneous Memory Buffers* and the *Manual Partitioning of Global Memory* sections of the *Altera SDK for OpenCL Best Practices Guide*.

Related Information

- Altera SDK for OpenCL Best Practices Guide
- Disabling Burst-Interleaving of Global Memory (--no-interleaving <global_memory_type>) on page 1-63

Collecting Profile Data During Kernel Execution

In cases where kernel execution finishes after the host application completes, you can query the FPGA explicitly to collect profile data during kernel execution.

When you profile your OpenCL kernel during compilation, a **profile.mon** file is generated automatically. The profile data is then written to **profile.mon** after kernel execution completes on the FPGA. However, if kernel execution completes after the host application completes, no profiling information for that kernel

invocation will be available in the **profile.mon** file. In this case, you can modify your host code to acquire profiling information during kernel execution.

• To query the FPGA to collect profile data while the kernel is running, call the following host library call:

```
extern CL_API_ENTRY cl_int CL_API_CALL
clGetProfileInfoAltera(cl_event);
```

where cl_event is the kernel event. The kernel event you pass to this host library call must be the same one you pass to the clEnqueueNDRangeKernel call.

Important: If kernel execution completes before the invocation of clGetProfileInfoAltera, the function returns an event error message.

Caution: Invoking the clgetProfileInfoAltera function during kernel execution disables the profile counters momentarily so that the profiler can collect data from the FPGA. As a result, you will lose some profiling information during this interruption. If you call this function at very short intervals, the profile data might not accurately reflect the actual performance behavior of the kernel.

Consider the following example host code:

```
int main()
{
    ...
    clEnqueueNDRangeKernel (queue, kernel, ..., NULL);
    ...
    clEnqueueNDRangeKernel (queue, kernel, ..., NULL);
    ...
}
```

This host application runs on the assumption that a kernel launches twice and then completes. In the **profile.mon** file, there will be two sets of profile data, one for each kernel invocation. To collect profile data while the kernel is running, modify the host code in the following manner:

```
int main()
{
    ...
    clEnqueueNDRangeKernel (queue, kernel, ..., &event);

    //Get the profile data before the kernel completes
    clGetProfileInfoAltera (event);

    //Wait until the kernel completes
    clFinish (queue);
    ...
    clEnqueueNDRangeKernel (queue, kernel, ..., NULL);
    ...
}
```

The call to clGetProfileInfoAltera adds a new entry in the **profile.mon** file. The profiler GUI then parses this entry in the report.

For more information on the Altera Software Development Kit (SDK) for OpenCL (AOCL) profiler, refer to the following sections:

- Profile Your Kernel to Identify Performance Bottlenecks in the Altera SDK for OpenCL Best Practices Guide
- Profiling Your OpenCL Kernel

Related Information

- **Profiling Your OpenCL Kernel** on page 1-70

Modifying Host Program for Structure Parameter Conversion

If you convert any structure parameters to pointers-to-constant structures in your OpenCL kernel, you must modify your host application accordingly.

Perform the following changes to your host application:

1. Allocate a cl_mem buffer to store the structure contents.

Attention: You need a separate cl_mem buffer for every kernel that uses a different structure value.

- **2.** Set the structure kernel argument with a pointer to the structure buffer, not with a pointer to the structure contents.
- **3.** Populate the structure buffer contents before queuing the kernel. Perform one of the following steps to ensure that the structure buffer is populated before the kernel launches:
 - Queue the structure buffer on the same command queue as the kernel queue.
 - Synchronize separate kernel queues and structure buffer queues with an event.
- **4.** When your application no longer needs to call a kernel that uses the structure buffer, release the cl_mem buffer.

- Matching Data Layouts of Host and Kernel Structure Data Types on page 1-36

Allocating Shared Memory for OpenCL Kernels Targeting SoCs

Altera recommends that OpenCL kernels that run on Altera SoCs access shared memory instead of the FPGA DDR memory. FPGA DDR memory is accessible to kernels with very high bandwidths. However, read and write operations from the ARM CPU to FPGA DDR memory are very slow because they do not use direct memory access (DMA). Reserve FPGA DDR memory only for passing temporary data between kernels or within a single kernel for testing purposes.

Before you begin

- **Note: 1.** Mark the shared buffers between kernels as volatile to ensure that buffer modification by one kernel is visible to the other kernel.
 - **2.** To access shared memory, you only need to modify the host code. Modifications to the kernel code are unnecessary.
 - 3. You cannot use the library function malloc or the operator new to allocate physically shared memory. Also, the CL_MEM_USE_HOST_PTR flag does not work with shared memory.
 - In DDR memory, shared memory must be physically contiguous. The FPGA cannot consume virtually contiguous memory without a scatter-gather direct memory access (SG-DMA)

controller core. The \mathtt{malloc} function and the \mathtt{new} operator are for accessing memory that is virtually contiguous.

4. CPU caching is disabled for the shared memory.

The ARM CPU and the FPGA can access the shared memory simultaneously. You do not need to include the clenqueueReadBuffer and clenqueueWriteBuffer calls in your host code to make data visible to either the FPGA or the CPU.

• To allocate and access shared memory, structure your host code in a similar manner as the following example:

```
cl_mem src = clCreateBuffer(..., CL_MEM_ALLOC_HOST_PTR, size, ...);
int *src_ptr = (int*)clEnqueueMapBuffer (..., src, size, ...);
*src_ptr = input_value; //host writes to ptr directly
clSetKernelArg (..., src);
clEnqueueNDRangeKernel(...);
clFinish();
printf ("Result = %d\n", *dst_ptr); //result is available immediately
clEnqueueUnmapMemObject(..., src, src_ptr, ...);
clReleaseMemObject(src); // actually frees physical memory
```

You can include the <code>CONFIG_CMA_SIZE_MBYTES</code> kernel configuration option to control the maximum total amount of shared memory available for allocation. In practice, the total amount of allocated shared memory is smaller than the value of <code>CONFIG_CMA_SIZE_MBYTES</code>.

- Important: 1. If your target board has multiple DDR memory banks, the clcreateBuffer(..., CL_MEM_READ_WRITE, ...) function allocates memory to the nonshared DDR memory banks. However, if the FPGA has access to a single DDR bank that is shared memory, then clcreateBuffer(..., CL_MEM_READ_WRITE, ...) allocates to shared memory, similar to using the CL_MEM_ALLOC_HOST_PTR flag.
 - 2. The shared memory that you request with the clcreateBuffer(..., CL_MEM_ALLOC_HOST_PTR, size, ...) function is allocated in the Linux OpenCL kernel driver, and it relies on the contiguous memory allocator (CMA) feature of the Linux kernel. For detailed information on enabling and configuring the CMA, refer to the Recompiling the Linux Kernel and the OpenCL Linux Kernel Driver section of the Altera Cyclone V SoC Development Kit Reference Platform Porting Guide.
- To transfer data from shared hard processor system (HPS) DDR to FPGA DDR efficiently, include a kernel that performs the memcpy function, as shown below.

```
__attribute__((num_simd_work_items(8)))
mem_stream(__global uint * src, __global uint * dst)
{
    size_t gid = get_global_id(0);
    dst[gid] = src[gid];
}
```

Attention: Allocate the src pointer in the HPS DDR as shared memory using the CL_MEM_ALLOC_HOST_PTR flag.

- If the host allocates constant memory to shared HPS DDR system and then modifies it after kernel execution, the modifications might not take effect. As a result, subsequent kernel executions might use outdated data. To prevent kernel execution from using outdated constant memory, perform one of the following tasks:
 - 1. Do not modify constant memory after its initialization.
 - 2. Create multiple constant memory buffers if you require multiple __constant data sets.
 - **3.** If available, allocate constant memory to the FPGA DDR on your accelerator board.

Altera Cyclone V SoC Development Kit Reference Platform Porting Guide

Managing Host Application

The Altera Software Development Kit (SDK) for OpenCL (AOCL) includes utility commands you can invoke to obtain information on flags and libraries necessary for compiling and linking your host application.

Attention: To cross-compile your host application to an SoC board, include the --arm option in your utility command.

Caution: For Linux systems, if you debug your host application using the GNU Project Debugger (GDB), invoke the following command prior to running the host application:

handle SIG44 nostop

Without this command, the GDB debugging process terminates with the following error message:

Program received signal SIG44, Real-time event 44.

Displaying Example Makefile Fragments (example-makefile or makefile)

To display example Makefile fragments for compiling and linking a host application against host runtime libraries available with the Altera Software Development Kit (SDK) for OpenCL, invoke the example-makefile or makefile utility command.

 At a command prompt, invoke the aocl example-makefile or aocl makefile utility command.

The software displays an output similar to the following:

```
The following are example Makefile fragments for compiling and linking
a host program against the host runtime libraries included with the
Altera SDK for OpenCL.
Example GNU makefile on Linux, with GCC toolchain:
   AOCL_COMPILE_CONFIG=$(shell aocl compile-config)
  AOCL_LINK_CONFIG=$(shell aocl link-config)
  host_prog : host_prog.o
        g++ -o host_prog host_prog.o $(AOCL_LINK_CONFIG)
  host_prog.o : host_prog.cpp
        g++ -c host_prog.cpp $(AOCL_COMPILE_CONFIG)
Example GNU makefile on Windows, with Microsoft Visual C++ command line compiler:
   AOCL_COMPILE_CONFIG=$(shell aocl compile-config)
  AOCL_LINK_CONFIG=$(shell aocl link-config)
  host_prog.exe : host_prog.obj
        link -nologo /OUT:host_prog.exe host_prog.obj $(AOCL_LINK_CONFIG)
  host_prog.obj : host_prog.cpp
        cl /MD /Fohost_prog.obj -c host_prog.cpp $(AOCL_COMPILE_CONFIG)
Example GNU makefile cross-compiling to ARM SoC from Linux or Windows, with
Linaro GCC cross-compiler toolchain:
   CROSS-COMPILER=arm-linux-gnueabihf-
  AOCL_COMPILE_CONFIG=$(shell aocl compile-config --arm)
  AOCL_LINK_CONFIG=$(shell aocl link-config --arm)
  host_prog : host_prog.o
        $(CROSS-COMPILER)g++ -o host_prog host_prog.o $(AOCL_LINK_CONFIG)
  host_prog.o : host_prog.cpp
        $(CROSS-COMPILER)g++ -c host_prog.cpp $(AOCL_COMPILE_CONFIG)
```

Compiling and Linking Your Host Application

The OpenCL host application uses standard OpenCL runtime application programming interfaces (APIs) to manage device configuration, data buffers, kernel launches, and synchronization. The host application also contains functions such as file I/O, or portions of the source code that do not run on an accelerator device. The Altera Software Development Kit (SDK) for OpenCL (AOCL)Runtime Environment (RTE) for OpenCL includes utility commands you can invoke to obtain information on C header files describing the OpenCL APIs, and board-specific memory-mapped device (MMD) and host runtime libraries with which you must link your host application.

Important: For Windows systems, you must add the /MD flag to link the host runtime libraries against the multithreaded dynamically-linked library (DLL) version of the Microsoft C Runtime library. You must also compile your host application with the /MD compilation flag, or use the /NODEFAULTLIB linker option to override the selection of runtime library.

Altera SDK for OpenCL Programming Guide

Remember: Include the path to the *ALTERAOCLSDKROOT/host/<OS_platform>/bin* folder in your library search path when you run your host application.

Displaying Flags for Compiling Host Application (compile-config) on page 1-50

To display a list of flags necessary for compiling a host application, invoke the compile-config utility command.

Displaying Paths to OpenCL Host Runtime and MMD Libraries (ldflags) on page 1-50

To display the paths necessary for linking a host application to the OpenCL host runtime and memory-mapped device (MMD) libraries, invoke the ldflags utility command.

Listing OpenCL Host Runtime and MMD Libraries (Idlibs) on page 1-50

To display the names of the OpenCL host runtime and memory-mapped device (MMD) libraries necessary for linking a host application, invoke the ldlibs utility command.

Displaying Information on OpenCL Host Runtime and MMD Libraries (link-config or linkflags) on page 1-51

To display a list of flags necessary for linking a host application with OpenCL host runtime and memory-mapped device (MMD) libraries, invoke the link-config or linkflags utility command.

Displaying Flags for Compiling Host Application (compile-config)

To display a list of flags necessary for compiling a host application, invoke the compile-config utility command.

- 1. At a command prompt, invoke the accl compile-config utility command.

 The software displays the path to the folder or directory in which the OpenCL application programming interface (API) header files reside. For example:
 - For Windows systems, the path is -I%ALTERAOCLSDKROOT%/host/include
 - For Linux systems, the path is -I\$ALTERAOCLSDKROOT/host/include

where *ALTERAOCLSDKROOT* points to the location of the software installation.

2. Add this path to your C preprocessor.

Attention: In your host source, include the **opencl.h** OpenCL header file, located in the **ALTERAOCLSDK-ROOT/host/include/CL** folder or directory.

Displaying Paths to OpenCL Host Runtime and MMD Libraries (Idflags)

To display the paths necessary for linking a host application to the OpenCL host runtime and memory-mapped device (MMD) libraries, invoke the ldflags utility command.

- At a command prompt, invoke the aocl ldflags utility command.

 The software displays the paths for linking your host application with the following libraries:
 - 1. The OpenCL host runtime libraries that provide OpenCL platform and runtime application programming interfaces (APIs). The OpenCL host runtime libraries are available in the *ALTERAOCLSDKROOT*/host/<*OS_platform>*/lib directory.
 - 2. The path to the Custom Platform-specific MMD libraries. The MMD libraries are available in the

 <box>board_family_name>/<OS_platform>/lib</br>
 directory of your Custom Platform.

Listing OpenCL Host Runtime and MMD Libraries (Idlibs)

To display the names of the OpenCL host runtime and memory-mapped device (MMD) libraries necessary for linking a host application, invoke the ldlibs utility command.

Displaying Information on OpenCL Host Runtime and MMD Libraries (link-config or linkflags)

- At a command prompt, invoke the aocl ldlibs utility command.
 The software lists the OpenCL host runtime libraries residing in the ALTERAOCLSDKROOT/host/
 <OS_platform>/lib directory. It also lists the Custom Platform-specific MMD libraries residing in the /
 <board_family_name>/<OS_platform>/lib directory of your Custom Platform.
 - For Windows systems, the output might resemble the following example:

```
alterahalmmd.lib
<board_vendor_name>_<board_family_name>_mmd.[lib|so|a|dll]
alteracl.lib
acl_emulator_kernel_rt.lib
pkg_editor.lib
libelf.lib
acl_hostxml.lib
```

• For Linux systems, the output might resemble the following example:

```
-lalteracl
-ldl
-lacl_emulator_kernel_rt
-lalterahalmmd
-l<board_vendor_name>_<board_family_name>_mmd
-lelf
-lrt
-lstdc++
```

Displaying Information on OpenCL Host Runtime and MMD Libraries (link-config or linkflags)

To display a list of flags necessary for linking a host application with OpenCL host runtime and memory-mapped device (MMD) libraries, invoke the link-config or linkflags utility command.

This utility command combines the functions of the ldflags and ldlibs utility commands.

- 1. At a command prompt, invoke the aocl link-config or aocl linkflags command.

 The software displays the link options for linking your host application with the following libraries:
 - 1. The path to and the names of OpenCL host runtime libraries that provide OpenCL platform and runtime application programming interfaces (APIs). The OpenCL host runtime libraries are available in the *ALTERAOCLSDKROOT*/host/<05_platform>/lib directory.
 - **2.** The path to and the names of the Custom Platform-specific MMD libraries. The MMD libraries are available in the **<board_family_name>**/**<OS_platform>**/**lib** directory of your Custom Platform.

• For Windows systems, the link options might resemble the following example output:

```
/libpath:%ALTERAOCLSDKROOT%/board/<board_name>/windows64/lib /libpath:%ALTERAOCLSDKROOT%/host/windows64/lib alterahalmmd.lib <board_vendor_name>_<board_family_name>_mmd.[lib|so|a|dll] alteracl.lib acl_emulator_kernel_rt.lib pkg_editor.lib libelf.lib acl_hostxml.lib
```

• For Linux systems, the link options might resemble the following example output:

```
-L/$ALTERAOCLSDKROOT/board/<board_name>/linux64/lib
-L/$ALTERAOCLSDKROOT/host/linux64/lib
-lalterac
-ldl
-lacl_emulator_kernel_rt
-lalterahalmmd
-l<board_vendor_name>_<board_family_name>_mmd
-lelf
-lrt
-lstdc++
```

Programming an FPGA via the Host

The Altera Offline Compiler (AOC) is an offline compiler that compiles kernels independently of the host application. To load the kernels into the OpenCL runtime, include the clcreateProgramWithBinary function in your host application.

- **1.** Compile your OpenCL kernel with the AOC to create the Altera Offline Compiler Executable file (.aocx).
- 2. Include the clcreateProgramWithBinary function in your host application to create the cl_program OpenCL program objects from the .aocx file.
- **3.** Include the clBuildProgram function in your host application to create the program executable for the specified device.

Below is an example host code on using clcreateProgramWithBinary to program an FPGA device:

```
size_t lengths[1];
unsigned char* binaries[1] ={NULL};
cl_int status[1];
cl_int error;
cl_program program;
const char options[] = "";
FILE *fp = fopen("program.aocx","rb");
fseek(fp,0,SEEK_END);
lengths[0] = ftell(fp);
binaries[0] = (unsigned char*)malloc(sizeof(unsigned char)*lengths[0]);
rewind(fp);
fread(binaries[0],lengths[0],1,fp);
fclose(fp);
program = clCreateProgramWithBinary(context,
                                     1,
                                     device_list,
                                     lengths,
                                     (const unsigned char **)binaries,
                                     status,
```

&error);
clBuildProgram(program,1,device_list,options,NULL,NULL);

If the clBuildProgram function executes successfully, it returns CL_SUCCESS.

- **4.** Create kernel objects from the program executable using the clCreateKernelsInProgram or clCreateKernel function.
- **5.** Include the kernel execution function to instruct the host runtime to execute the scheduled kernel(s) on the FPGA.
 - To enqueue a command to execute an NDRange kernel, use clenqueueNDRangeKernel.
 - To enqueue a single work-item kernel, use clenqueueTask.

You can load multiple FPGA programs into memory, which the host then uses to reprogram the FPGA as required.

For more information on these OpenCL host runtime application programming interface (API) calls, refer to the *OpenCL Specification version 1.0*.

Related Information

OpenCL Specification version 1.0

Programming Multiple FPGA Devices

If you install multiple FPGA devices in your system, you can direct the host runtime to program a specific FPGA device by modifying your host code.

Important: You may only program multiple FPGA devices from the *same* Custom Platform because the *AOCL_BOARD_PACKAGE_ROOT* environment variable points to the location of a single Custom Platform.

You can present up to 16 FPGA devices to your system in the following manner:

- Multiple FPGA accelerator boards, each consisting of a single FPGA.
- Multiple FPGAs on a single accelerator board that connects to the host system via a PCI Express (PCIe) switch.
- Combinations of the above.

The host runtime can load kernels onto each and every one of the FPGA devices. The FPGA devices can then operate in a parallel fashion.

1. Probing the OpenCL FPGA Devices on page 1-53

The host must identify the number of OpenCL FPGA devices installed into the system.

2. Querying Device Information on page 1-54

You can direct the host to query information on your OpenCL FPGA devices.

3. Loading Kernels for Multiple FPGA Devices on page 1-55

If your system contains multiple FPGA devices, you can create specific cl_program objects for each FPGA and load them into the OpenCL runtime.

Probing the OpenCL FPGA Devices

The host must identify the number of OpenCL FPGA devices installed into the system.

- 1. To query a list of FPGA devices installed in your machine, invoke the aocl diagnose command.
- **2.** To direct the host to identify the number of OpenCL FPGA devices, add the following lines of code to your host application:

For example, on a system with two OpenCL FPGA devices, ciDeviceCount has a value of 2, and cdDevices contains a list of two device IDs (cl_device_id).

Related Information

Querying the Device Name of Your FPGA Board (diagnose) on page 1-11

Querying Device Information

You can direct the host to query information on your OpenCL FPGA devices.

• To direct the host to output a list of OpenCL FPGA devices installed into your system, add the following lines of code to your host application:

```
char buf[1024];
for (unsigned i = 0; i < ciDeviceCount; i++);
{
    clGetDeviceInfo(cdDevices[i], CL_DEVICE_NAME, 1023, buf, 0);
    printf("Device %d: '%s'\n", i, buf);
}</pre>
```

When you query the device information, the host will list your FPGA devices in the following manner:

```
Device <N>: <board_name>: <name_of_FPGA_board>
Where:
```

<*N*> is the device number.

<board_name> is the board designation you use to target your FPGA device when you invoke the aoc
command

<name_of_FPGA_board> is the advertised name of the FPGA board.

For example, if you have two identical FPGA boards on your system, the host generates an output that resembles the following:

```
Device 0: board_1: Stratix V FPGA Board
Device 1: board_1: Stratix V FPGA Board
```

Note: The clGetDeviceInfo function returns the board type (for example, board_1) that the Altera Offline Compiler (AOC) lists on-screen when you invoke the aoc --list-boards command.

If your accelerator board contains more than one FPGA, each device is treated as a "board" and is given a unique name.

Related Information

Listing the Available FPGA Boards in Your Custom Platform (--list-boards) on page 1-9

Loading Kernels for Multiple FPGA Devices

If your system contains multiple FPGA devices, you can create specific cl_program objects for each FPGA and load them into the OpenCL runtime.

The following host code demonstrates the usage of the clCreateProgramWithBinary and createMulti-DeviceProgram functions to program multiple FPGA devices:

```
cl_program createMultiDeviceProgram(cl_context context,
                                     const cl_device_id *device_list,
                                     cl_uint num_devices,
                                     const char *aocx_name);
// Utility function for loading file into Binary String
unsigned char* load_file(const char* filename, size_t *size_ret)
   FILE *fp = fopen(aocx_name, "rb");
   fseek(fp,0,SEEK_END);
   size_t len = ftell(fp);
   char *result = (unsigned char*)malloc(sizeof(unsigned char)*len);
   rewind(fp);
   fread(result,len,1,fp);
   fclose(fp);
   *size_ret = len;
   return result;
}
//Create a Program that is compiled for the devices in the "device_list"
cl_program createMultiDeviceProgram(cl_context context,
                                     const cl_device_id *device_list,
                                     cl_uint num_devices,
                                     const char *aocx_name)
    printf("creating multi device program %s for %d devices\n",
           aocx_name, num_devices);
    const unsigned char **binaries =
       (const unsigned char**)malloc(num_devices*sizeof(unsigned char*));
    size_t *lengths=(size_t*)malloc(num_devices*sizeof(size_t));
    cl int err;
    for(cl_uint i=0; i<num_devices; i++)</pre>
       binaries[i] = load_file(aocx_name,&lengths[i]);
       if (!binaries[i])
          printf("couldn't load %s\n", aocx_name);
          exit(-1);
    }
    cl_program p = clCreateProgramWithBinary(context,
                                              num_devices,
                                              device_list,
                                              lengths,
                                              binaries,
                                              NULL,
                                              &err);
```

Compiling Your OpenCL Kernel

The Altera Software Development Kit (SDK) for OpenCL (AOCL) offers a list of compiler options that allows you to customize the kernel compilation process. For example, you can direct the Altera Offline Compiler (AOC) to target a specific FPGA board, generate reports, or implement optimization techniques.

Before you compile an OpenCL kernel, ensure that the environment variable *AOCL_BOARD_PACKAGE_ROOT* points to the location of the appropriate Custom Platform.

Attention: If you use the Altera Stratix V Network Reference Platform (s5_net), you must acquire and install the PLDA quick user datagram protocol (QuickUDP) intellectual property (IP) core license. Refer to the PLDA website for more information. If you use a Custom Platform that includes the QuickUDP IP core, refer to your board vendor's documentation for more information on the acquisition and installation of the QuickUDP IP license.

Caution: Improper installation of the QuickUDP IP license causes kernel compilation to fail with the following error message:

```
Error (292014): Can't find valid feature line for core PLDA QUICKTCP (73E1_AE12) in current license.
```

Note that the error has no actual dependency on the TCP Hardware Stack QuickTCP IP from PLDA.

Compiling a Kernel for a Big-Endian System (--big-endian)

To direct the Altera Offline Compiler (AOC) to compile your OpenCL kernel and generate a hardware configuration file for use in a big-endian system (for example, the IBM POWER system), include the --big-endian option in the aoc command.

If you create an OpenCL kernel program that targets a big-endian architecture, you have to specify bigendian ordering for the host and global memories. If not, the AOC automatically defaults to little-endian ordering.

• At a command prompt, invoke the aoc <your_kernel_filename>.cl --big-endian

Compiling Your Kernel to Create Hardware Configuration File

You can compile an OpenCL kernel and create the hardware configuration file (that is, the Altera Offline Compiler Executable file (.aocx)) in a single step.

Altera recommends that you use this one-step compilation strategy under the following circumstances:

- After you optimize your kernel via the Altera Software Development Kit (SDK) for OpenCL design flow, and you are now ready to create the **.aocx** file for deployment onto the FPGA.
- You have a simple kernel that does not require any optimization.
- To compile the kernel and generate the **.aocx** file in one step, invoke the aoc <your_kernel_filename>.cl command.

Compiling Your Kernel without Building Hardware (-c)

To direct the Altera Offline Compiler (AOC) to compile your OpenCL kernel and generate a Quartus II hardware design project without creating a hardware configuration file, include the -c option in your aoc command.

- At a command prompt, invoke the aoc -c < your_kernel_filename>.cl command. When you invoke the aoc command with the -c flag, the AOC compiles the kernel and creates the following files and directories:
 - The Altera Offline Compiler Object file (.aoco). The AOC creates the .aoco file in a matter of seconds to minutes.
 - A <**your_kernel_filename>** folder or subdirectory. It contains intermediate files that the Altera Software Development Kit (SDK) for OpenCL (AOCL) uses to build the hardware configuration file necessary for FPGA programming.

Specifying the Location of Header Files (-I <directory>)

To add a directory to the list of directories that the Altera Offline Compiler (AOC) searches for header files during kernel compilation, include the -I <directory> option in your acc command.

Altera SDK for OpenCL Programming Guide

If the header files are in the same directory as your kernel, you do not need to include the -I <directory> option in your aoc command. The AOC automatically searches the current folder or directory for header files.

• At a command prompt, invoke the aoc -I <directory> <your_kernel_filename>.cl command.

Caution: For Windows systems, ensure that your include path does not contain any trailing slashes. The AOC considers a trailing forward slash (/) or backward slash (\) as illegal.

The AOC generates an error message if you invoke the aoc command in the following manner:

```
aoc -I <drive>\<folder>\ ... \<subfolder>\
<your_kernel_filename>.cl

or
aoc -I <drive>/<folder>/ ... /<subfolder>/
<your_kernel_filename>.cl

The correct way to specify the include path is as follows:
aoc -I <drive>\<folder>\ ... \<subfolder>
<your_kernel_filename>.cl

or
aoc -I <drive>/<folder>/ ... /<subfolder>
<your_kernel_filename>.cl
```

Specifying the Name of an AOC Output File (-o <filename>)

To specify the name of an Altera Offline Compiler Object file (.aoco) or an Altera Offline Compiler Executable file (.aocx), include the -o <filename> option in your aoc command.

- If you implement the multistep compilation flow, specify the names of the output files in the following manner:
 - 1. To specify the name of the .aoco file that the Altera Offline Compiler (AOC) creates during an intermediate compilation step, invoke the aoc -c -o <your_object_filename>.aoco <your kernel_filename>.cl command.
 - 2. To specify the name of the .aocx file that the AOC creates during the final compilation step, invoke the aoc -o <your_executable_filename>.aocx <your_object_filename>.aoco command.
- If you implement the one-step compilation flow, specify the name of the <code>.aocx</code> file by invoking the aoc <code>-o <your_executable_filename>.aocx <your_kernel_filename>.cl command.</code>

Compiling a Kernel for a Specific FPGA Board (--board <board_name>)

To compile your OpenCL kernel for a specific FPGA board, include the --board

board_name> option in the aoc command.

Before you begin

To compile a kernel for a specific board in your Custom Platform, you must first set the environment variable *AOCL_BOARD_PACKAGE_ROOT* to point to the location of your Custom Platform.

Attention: If you want to program multiple FPGA devices, you may select board types that are available in the same Custom Platform because *AOCL_BOARD_PACKAGE_ROOT* only points to the location of one Custom Platform.

When you compile your kernel by including the --board

command, the Altera Offline Compiler (AOC) defines the preprocessor macro

AOCL_BOARD_

board_name> to be 1, which allows you to compile device-optimized code in your kernel.

1. To obtain the names of the available FPGA boards in your Custom Platform, invoke the acc -- list-boards command.

For example, the AOC generates the following output:

```
Board List:
FPGA_board_1
```

where FPGA_board_1 is the <board_name>.

2. To compile your OpenCL kernel for FPGA_board_1, invoke the aoc --board FPGA_board_1 <your_kernel_filename>.cl command.

The AOC defines the preprocessor macro AOCL_BOARD_FPGA_board_1 to be 1 and compiles kernel code that targets FPGA_board_1.

Tip: To readily identify compiled kernel files that target a specific FPGA board, Altera recommends that you rename the kernel binaries by including the −o option in the aoc command.

To target your kernel to FPGA_board_1 in the one-step compilation flow, invoke the following command:

```
aoc --board FPGA_board_1 <your_kernel_filename>.cl -o
<your_executable_filename>_FPGA_board_1.aocx
```

To target your kernel to FPGA_board_1 in the multistep compilation flow, perform the following tasks:

1. Invoke the following command to generate the Altera Offline Compiler Object File (.aoco):

```
aoc -c --board FPGA_board_1 <your_kernel_filename>.cl
-o <my_object_filename>_FPGA_board_1.aoco
```

2. Invoke the following command to generate the Altera Offline Compiler Executable file (.aocx):

```
aoc --board FPGA_board_1
<your_object_filename>_FPGA_board_1.aoco -o
<your_executable_filename>_FPGA_board_1.aocx
```

If you have an accelerator board consisting of two FPGAs, each FPGA device has an equivalent "board" name (for example, board_fpga_1 and board_fpga_2). To target a **kernel_1.cl** to board_fpga_1 and a **kernel_2.cl** to board_fpga_2, invoke the following commands:

```
aoc --board board_fpga1 kernel_1.cl
```

aoc --board board_fpga2 kernel_2.cl

Related Information

Specifying the Name of an AOC Output File (-o <filename>) on page 1-58

Defining Preprocessor Macros to Specify Kernel Parameters (-D <macro_name>)

The Altera Offline Compiler (AOC) supports preprocessor macros that allow you to pass macro definitions and compile code on a conditional basis.

- To pass a preprocessor macro definition to the AOC, invoke the aoc -D <macro_name>
 <kernel_filename>.cl command.
- To override the existing value of a defined preprocessor macro, invoke the aoc -D <marco_name>=<value> <kernel_filename>.cl command.
 Consider the following code snippet for the kernel sum:

To override the UNROLL_FACTOR of 1 and set it to 4, invoke the aoc -D UNROLL_FACTOR=4 sum.cl command. Invoking this command is equivalent to replacing the line #define UNROLL_FACTOR 1 with #define UNROLL_FACTOR 4 in the sum kernel source code.

To use preprocessor macros to control how the AOC optimizes your kernel without modifying your kernel source code, invoke the aoc -o <hardware_filename>.aocx -D <macro_name>=<value> <kernel_filename>.cl
 Where:

-○ is the AOC option you use to specify the name of the Altera Offline Compiler Executable file (.aocx) that the AOC generates.

<hardware_filename> is the name of the .aocx file that the AOC generates using the preprocessor macro value you specify.

Tip: To preserve the results from both compilations on your file system, compile your kernels as separate binaries by using the -o flag of the aoc command.

For example, if you want to compile the same kernel multiple times with required work-group sizes of 64 and 128, you can define a WORK_GROUP_SIZE preprocessor macro for the kernel attribute regd_work_group_size, as shown below:

Compile the kernel multiple times by typing the following commands:

```
aoc -o myKernel_64.aocx -D WORK_GROUP_SIZE=64 myKernel.cl
aoc -o myKernel 128.aocx -D WORK GROUP SIZE=128 myKernel.cl
```

Altera SDK for OpenCL Programming Guide

Generating Compilation Progress Report (-v)

To direct the Altera Offline Compiler (AOC) to report on the progress of a compilation, include the -v option in your acc command.

• To direct the AOC to report on the progress of a full compilation, invoke the aoc -v <your_kernel_filename>.cl command.

The AOC generates a compilation progress report similar to the following example:

```
aoc: Environment checks are completed successfully.
You are now compiling the full flow!!
aoc: Selected target board s5_net
aoc: Running OpenCL parser....
aoc: OpenCL parser completed successfully.
aoc: Compiling....
aoc: Linking with IP library ...
aoc: First stage compilation completed successfully.
aoc: Setting up project for CvP revision flow....
aoc: Hardware generation completed successfully.
```

• To direct the AOC to report on the progress of an intermediate compilation step that does not build hardware, invoke the aoc -c -v < your_kernel_filename > . cl command.

The AOC generates a compilation progress report similar to the following example:

```
aoc: Environment checks are completed successfully.
aoc: Selected target board s5_net
aoc: Running OpenCL parser....
aoc: OpenCL parser completed successfully.
aoc: Compiling....
aoc: Linking with IP library ...
aoc: First stage compilation completed successfully.
aoc: To compile this project, run "aoc <your_kernel_filename>.aoco"
```

• To direct the AOC to report on the progress of a compilation for emulation, invoke the aoc - march=emulator -v < your_kernel_filename > . cl command.

The AOC generates a compilation progress report similar to the following example:

```
aoc: Environment checks are completed successfully. You are now compiling the full flow!! aoc: Selected target board s5_net aoc: Running OpenCL parser...ex aoc: OpenCL parser completed successfully. aoc: Compiling for Emulation .... aoc: Emulator Compilation completed successfully. Emulator flow is successful.
```

Displaying the Estimated Resource Usage Summary On-Screen (--report)

By default, the Altera Offline Compiler (AOC) estimates hardware resource usage during compilation. The AOC factors in the usage of external interfaces such as PCI Express (PCIe), memory controller, and direct memory access (DMA) engine in its calculations. During kernel compilation, the AOC generates an estimated resource usage summary in the <code><your_kernel_filename>.log</code> file within the <code><your_kernel_filename></code> directory. To review the estimated resource usage summary on-screen, include the <code>--report</code> option in the <code>aoc</code> command.

You can review the estimated resource usage summary without performing a full compilation. To review the summary on-screen prior to generating the hardware configuration file, include the -c option in your aoc command.

• At a command prompt, invoke the aoc -c < your_kernel_filename > .cl --report command.

The AOC generates an output similar to the following example:

aoc: Selected target board s5_ref

; Estimated Resource Usage Summary		+ ;
; Resource	+ Usage +	; ;
; Logic utilization ; Dedicated logic registers ; Memory blocks ; DSP blocks	; 13%; 5%; 12%; 0%	;;;;

Related Information

Compiling Your Kernel without Building Hardware (-c) on page 1-57

Suppressing AOC Warning Messages (-W)

To suppress all warning messages, include the -W option in your aoc command.

• At a command prompt, invoke the aoc -W <your_kernel_filename>.cl command.

Converting AOC Warning Messages into Error Messages (-Werror)

To convert all warning messages into error messages, include the -Werror option in your accommand.

• At a command prompt, invoke the aoc -Werror <your_kernel_filename>.cl command.

Adding Source References to Optimization Reports (-g)

Include the -g option in your aoc command to add source references to compilation reports.

When you compile a single work-item kernel, the Altera Offline Compiler (AOC) automatically generates an optimization report in the <code><your_kernel_filename>.log</code> file in the <code><your_kernel_filename></code> subfolder or subdirectory. Adding source information such as line numbers and variable names in the optimization report allows you to pinpoint the locations of loop-carried dependencies in your kernel source code.

• To add source information in the optimization report, invoke the aoc -g <your_kernel_filename>.cl command.

Disabling Burst-Interleaving of Global Memory (--no-interleaving <global_memory_type>)

The Altera Offline Compiler (AOC) cannot burst-interleave global memory across different memory types. You can disable burst-interleaving for all global memory banks of the same type and manage them manually by including the --no-interleaving <global_memory_type> option in your acc command. Manual partitioning of memory buffers overrides the default burst-interleaved configuration of global memory.

Caution: The --no-interleaving option requires a global memory type parameter. If you do not specify a memory type, the AOC issues an error message.

- To direct the AOC to disable burst-interleaving for the default global memory, invoke the aoc <pvour_kernel_filename>.cl --no-interleaving default command.
 Your accelerator board might include multiple global memory types. To identify the default global memory type, refer to board vendor's documentation for your Custom Platform.
- For a heterogeneous memory system, to direct the AOC to disable burst-interleaving of a specific global memory type, perform the following tasks:
 - 1. Consult the **board_spec.xml** file of your Custom Platform for the names of the available global memory types (for example, DDR and quad data rate (QDR)).
 - 2. To disable burst-interleaving for one of the memory types (for example, DDR), invoke the acc <your_kernel_filename>.cl --no-interleaving DDR command.
 The AOC enables manual partitioning for the DDR memory bank, and configures the other memory bank in a burst-interleaved fashion.
 - 3. To disable burst-interleaving for more than one type of global memory buffers, include a --no-interleaving <global_memory_type> option for each global memory type. For example, to disable burst-interleaving for both DDR and QDR, invoke the aoc <your_kernel_filename>.cl --no-interleaving DDR --no-interleaving ODR command.

Caution: Do not pass a buffer as kernel arguments that associate it with multiple memory technologies.

Configuring Constant Memory Cache Size (--const-cache-bytes <N>)

Include the --const-cache-bytes <*N*> flag in your acc command to direct the Altera Offline Compiler (AOC) to configure the constant memory cache size (rounded up to the closest power of 2).

The default constant cache size is 16 kilobytes (kB).

• To configure the constant memory cache size, invoke the aoc --const-cache-bytes <*N*> <*your_kernel_filename*>.cl command, where <*N*> is the cache size in bytes. For example, to configure a 32 kB cache during compilation of the OpenCL kernel myKernel.cl, invoke the aoc --const-cache-bytes 32768 myKernel.cl command.

Note: This argument has no effect if none of the kernels uses the __constant address space.

Relaxing the Order of Floating-Point Operations (--fp-relaxed)

Include the --fp-relaxed option in your acc command to direct the Altera Offline Compiler (AOC) to relax the order of arithmetic floating-point operations using a balanced tree hardware implementation.

Implementing a balanced tree structure leads to more efficient hardware at the expense of numerical variation in results.

Caution: To implement this optimization control, your program must be able to tolerate small variations in the floating-point results.

• To direct the AOC to execute a balanced tree hardware implementation, invoke the aoc --fp-relaxed <your_kernel_filename>.cl command.

Reducing Floating-Point Rounding Operations (--fpc)

Include the --fpc option in your aoc command to direct the Altera Offline Compiler (AOC) to remove intermediary floating-point rounding operations and conversions whenever possible, and to carry additional bits to maintain precision.

Implementing this optimization control also changes the rounding mode. It rounds towards zero only at the end of a chain of floating-point arithmetic operations (that is, multiplications, additions, and subtractions).

• To direct the AOC to reduce the number of rounding operations, invoke the aoc --fpc <your_kernel_filename>.cl command.

Emulating and Debugging Your OpenCL Kernel

Use the Altera Software Development Kit (SDK) for OpenCL (AOCL) emulator to assess the functionality of your kernel.

The AOCL emulator generates an Altera Offline Compiler Executable file (.aocx) that executes on x86-64 Windows or Linux host. This feature allows you to emulate the functionality of your kernel and iterate on your design without executing it on the actual FPGA each time. For Linux platform, you can also use the emulator to perform functional debug.

Attention: Emulation is not available to OpenCL kernel designs targeting the Cyclone V SoC Development Kit

1. Modifying Channels Kernel Code for Emulation on page 1-65

To emulate applications with a channel that reads or writes to an I/O channel, modify your kernel to add a read or write channel that replaces the I/O channel, and make the source code that uses it is conditional.

2. Compiling a Kernel for Emulation (-march=emulator) on page 1-67

To compile an OpenCL kernel for emulation, include the -march=emulator option in your accommand.

- 3. Emulating Your OpenCL Kernel on page 1-67
 - To emulate your OpenCL kernel, run the emulation Altera Offline Executable file (.aocx) on the platform on which you build your kernel.
- 4. Debugging Your OpenCL Kernel on Linux on page 1-68
 - For Linux systems, you can direct the Altera Software Development Kit (SDK) for OpenCL emulator to run your OpenCL kernel in the debugger and debug it functionally as part of the host application.
- 5. Limitations of the AOCL Emulator on page 1-69
 - The Altera Software Development Kit (SDK) for OpenCL (AOCL) emulator feature has some limitations.

Modifying Channels Kernel Code for Emulation

The emulator emulates kernel-to-kernel channels. It does not support the emulation of I/O channels that interface with input or output features of your FPGA board. To emulate applications with a channel that reads or writes to an I/O channel, modify your kernel to add a read or write channel that replaces the I/O channel, and make the source code that uses it is conditional.

Send Feedback

Before you begin

The Altera Software Development Kit (SDK) for OpenCL (AOCL) does not set the EMULATOR macro definition. You must set it manually either from the command line or in the source code.

Consider the following kernel example:

To enable the emulator to emulate a kernel with a channel that interfaces with an I/O channel, perform the following tasks:

- 1. Modify the kernel code in one of the following manner:
 - Add a matching write_channel_altera call such as the one shown below.

```
#ifdef EMULATOR
__kernel void io_in (__global char * restrict arr, int size)
{
    for (unsigned i=0; i<size; i++)
        {
        ulong4 data = arr[i]; //arr[i] being an alternate data source
        write_channel_altera(inchannel, data);
    }
}
#endif</pre>
```

• Replace the I/O channel access with a memory access, as shown below:

```
_kernel void send (int size)
{
    for (unsigned i=0; i < size; i++)
    {
        #ifndef EMULATOR

        ulong4 data = read_channel_altera(inchannel);

    #else
        ulong4 data = arr[i]; //arr[i] being an alternate data source
    #endif
    //statements
    }
}</pre>
```

2. Modify the host application to create and start this conditional kernel during emulation.

Related Information

Implementing I/O Channels Using the io Channels Attribute on page 1-25

Compiling a Kernel for Emulation (-march=emulator)

To compile an OpenCL kernel for emulation, include the -march=emulator option in your accommand.

Before you begin

Before you perform kernel emulation, ensure that you install a Custom Platform from your board vendor for your FPGA accelerator boards. Ensure that the environment variable $AOCL_BOARD_PACKAGE_ROOT$ points to the location of the Custom Platform. Alternatively, if your kernel targets a board from an Altera Software Development Kit (SDK) for OpenCL Reference Platform, set $AOCL_BOARD_PACKAGE_ROOT$ to the path of the Reference Platform (for example, ALTERAOCLSDKROOT/board/<Reference_Platform_name>).

- To create kernel programs executable on x86-64 host systems, invoke the acc -march=emulator <your_kernel_filename>.cl command.
- To compile a kernel for emulation that targets a specific board, invoke the aoc -march=emulator --board

 -board_name> <your_kernel_filename>.cl command.
- For Linux systems, to direct the Altera Offline Compiler (AOC) to enable symbolic debug support for the debugger, invoke the aoc -march=emulator -g <your_kernel_filename>.cl command.

Enabling AOC debug support allows you to pinpoint the origins of functional errors in your kernel source code.

Related Information

- Adding Source References to Optimization Reports (-g) on page 1-63

Emulating Your OpenCL Kernel

To emulate your OpenCL kernel, run the emulation Altera Offline Executable file (.aocx) on the platform on which you build your kernel.

Before you begin

To emulate your kernels on Windows systems, you need the Microsoft linker and additional compilation time libraries.

- Ensure that your *PATH* environment variable setting includes the path to the Microsoft **LINK.EXE** file.
 - The **LINK.EXE** file is available with Microsoft Visual Studio.
- Ensure that your *LIB* environment variable setting includes the path to the Microsoft compilation time libraries.

The compilation time libraries are available with Microsoft Visual Studio.

Tip: In a system with multiple devices, kernels on different boards cannot interact with each other directly. Therefore, in most cases, you can simply emulate one device at a time to verify kernel functionality. There are times when a kernel on one board processes data that another board generates. In these situations, you might have to run kernels from multiple boards in the same emulation session to verify kernel functionality efficiently.

To emulate your kernel, perform the following steps:

- 1. Run the utility command aocl linkflags to find out which libraries are necessary for building a host application. The software lists the libraries for both emulation and nonemulation compilation flows.
- **2.** Build a host application and link it to the libraries from Step 1.
- **3.** Ensure that the **<your_kernel_filename>.aocx** file is in a location where the host can find it, preferably the current working directory.
- - **a.** To run emulation on multiple devices, invoke the env CL_CONTEXT_EMULATOR_DEVICE_ALTERA=<number_of_devices> command. This command specifies the number of identical emulation devices that the emulator needs to generate.

Important: Ensure that you build your host application for programming multiple FPGA devices.

5. If you change your host or kernel program and you want to test it, only recompile the modified program and rerun emulation.

Each invocation of the emulated kernel creates a shared library copy called **process_ID>-libkernel.so in the tmp folder or directory, where process_ID> is a unique numerical value assigned to each emulation run.**

Displaying Information on OpenCL Host Runtime and MMD Libraries (link-config or linkflags) on page 1-51

Debugging Your OpenCL Kernel on Linux

For Linux systems, you can direct the Altera Software Development Kit (SDK) for OpenCL emulator to run your OpenCL kernel in the debugger and debug it functionally as part of the host application. The debugging feature allows you to debug the host and the kernel seamlessly. You can step through your code, set breakpoints, and examine and set variables.

Prior to debugging your kernel, you must perform the following tasks:

- 1. During program execution, the debugger cannot step from the host code to the kernel code. You must set a breakpoint before the actual kernel invocation by adding these lines:
 - a. break <your_kernel>

This line sets a breakpoint before the kernel.

b. continue

If you have not begun debugging your host, then type start instead.

2. The kernel is loaded as a shared library immediately before the host loads the kernels. The debugger does not recognize the kernel names until the host actually loads the kernel functions. As a result, the debugger will generate the following warning for the breakpoint you set before the execution of the first kernel:

```
Function "<your_kernel>" not defined.
```

Make breakpoint pending on future shared library load? (y or [n])

Answer y. After initial program execution, the debugger will recognize the function and variable names, and line number references for the duration of the session.

Caution: The emulator uses the OpenCL runtime to report some error details. For emulation, the runtime uses a default print out callback when you initialize a context via the clcreateContext function.

Note: Kernel debugging is independent of host debugging. Debug your host code in existing tools such as Microsoft Visual Studio Debugger for Windows and GNU Project Debugger (GDB) for Linux.

To compile your OpenCL kernel for debugging, perform the following steps:

1. To generate an Altera Offline Compiler Executable file (.aocx) for debugging that targets a specific accelerator board, invoke the aoc -march=emulator -g <your_kernel_filename>.cl --board <box/>board_name> command.

Attention: Specify the name of your FPGA board when you run your host application. To verify the name of the target board for which you compile your kernel, invoke the aoc - march=emulator -g -v <your_kernel_filename>.cl command. The AOC will display the name of the target FPGA board.

- 2. Run the utility command aocl linkflags to find out the additional libraries necessary to build a host application that supports kernel debugging.
- **3.** Build a host application and link it to the libraries from Step 2.
- **4.** Ensure that the **<your_kernel_filename>.aocx** file is in a location where the host can find it, preferably the current working directory.
- 5. To run the application, invoke the command env CL_CONTEXT_EMULATOR_DEVICE_ALTERA=

 context_emulator_device
 cyour_host_program_name, where

 when you compiled your kernel.
- **6.** If you change your host or kernel program and you want to test it, only recompile the modified program and rerun the debugger.

Limitations of the AOCL Emulator

The Altera Software Development Kit (SDK) for OpenCL (AOCL) emulator feature has some limitations.

1. Execution model

The emulator supports the same compilation modes as the FPGA variant. As a result, you must call the clCreateProgramBinary function to create cl_program objects for emulation.

2. Concurrent execution

Modeling of concurrent kernel executions has limitations. During execution, the emulator does not actually run interacting work-items in parallel. Therefore, some concurrent execution behaviors, such

as different kernels accessing global memory without a barrier for synchronization, might generate inconsistent emulation results between executions.

3. Kernel performance

The Altera Offline Compiler Executable file (.aocx) that you generate for emulation does not include any optimizations. Therefore, it might execute at a significantly slower speed than what an optimized kernel might achieve. In addition, because the emulator does not implement actual parallel execution, the execution time multiplies with the number of work-items that the kernel executes.

- **4.** The emulator executes the host runtime and the kernels in the same address space. Certain pointer or array usages in your host application might cause the kernel program to fail, and vice versa. Example usages include indexing external allocated memory and writing to random pointers. You may use memory leak detection tools such as Valgrind to analyze your program. However, the host might encounter a fatal error caused by out-of-bounds write operations in your kernel, and vice versa.
- 5. Emulation of channel behavior has limitations, especially for conditional channel operations where the kernel does not call the channel operation in every loop iteration. Therefore, the emulator might execute channel operations in a different order than on the hardware.

Profiling Your OpenCL Kernel

The Altera Software Development Kit (SDK) for OpenCL (AOCL) profiler measures and reports performance data collected during OpenCL kernel execution on the FPGA. The AOCL profiler relies on performance counters to gather kernel performance data. You can then review performance data in the profiler GUI.

- 1. Instrumenting the Kernel Pipeline with Performance Counters (--profile) on page 1-70 To instrument the OpenCL kernel pipeline with performance counters, include the --profile option of the acc command when you compile your kernel.
- Launching the AOCL Profiler GUI (report) on page 1-71
 You can use the Altera Software Development Kit (SDK) for OpenCL (AOCL) profiler report utility command to launch the profiler GUI.

Instrumenting the Kernel Pipeline with Performance Counters (--profile)

To instrument the OpenCL kernel pipeline with performance counters, include the --profile option of the acc command when you compile your kernel.

Attention: Instrumenting the Verilog code with performance counters increases hardware resource utilization (that is, increases FPGA area usage) and typically decreases performance.

- To instrument the Verilog code in the <your_kernel_filename>.aocx Altera Offline Compiler Executable file with performance counters, invoke the aoc --profile <your_kernel_filename>.cl command.
- Run your host application to execute the your_kernel_filename.aocx Altera Offline Compiler
 Executable file on your FPGA. During kernel execution, the performance counters throughout the
 kernel pipeline collects profile information. The host saves the information in a profile.mon monitor
 description file in your current working directory.

Launching the AOCL Profiler GUI (report)

You can use the Altera Software Development Kit (SDK) for OpenCL (AOCL) profiler report utility command to launch the profiler GUI. The profiler GUI allows you to view kernel performance data statistics that the AOCL profiler collects during kernel execution.

The AOCL profiler stores performance data in a **profile.mon** file in your current working directory.

1. To launch the profiler GUI, invoke the aocl report <your_kernel_filename>.aocx
profile.mon utility command.

Conclusion

You are now familiar with the Altera Software Development Kit (SDK) for OpenCL design flow and the tools available to help you achieve your design goals. For more information on the support statuses of the OpenCL application programming interfaces (APIs) and programming language, refer to *Appendix A:* Support Statuses of OpenCL Features.

For in-depth information on optimizing your OpenCL kernel to maximize performance, refer to the *Altera SDK for OpenCL Best Practices Guide*.

Renamed Optional Extensions in Appendix B to Atomic Functions, and updated its content. Removed Platform Layer and Runtime Implementation from Appendix B.
May 2013	13.0.1	 Explicit memory fence functions are now supported; the entry is removed from the table OpenCL Programming Language Implementation. Updated the section Programming the Flash Memory of an FPGA. Added the section Modifying Your OpenCL Kernel by Specifying Kernel Attributes and Pragmas to introduce kernel attributes and pragmas that can be implemented to optimize kernel performance. Added the section Optimizing Global Memory Accesses to discuss data partitioning. Removed the section Programming the FPGA with the aocl program Command from Appendix A.

Date	Version	Changes
May 2013	13.0.0	 Updated compilation flow. Updated kernel compiler commands. Included Altera SDK for OpenCL Utility commands. Added the section OpenCL Programming Considerations. Updated flash programming procedure and moved it to Appendix A. Included a new clcreateProgramWithBinary FPGA hardware programming flow. Moved the hostless clcreateProgramWithBinary hardware programming flow to Appendix A under the title Programming the FPGA with the aocl program Command. Moved updated information on allocation limits and OpenCL language support to Appendix B.
Novembe r 2012	12.1.0	Initial release.

Support Statuses of OpenCL Features

2014.12.15

OCL002-14.1.0

The Altera Software Development Kit (SDK) for OpenCL (AOCL) supports the OpenCL Specification version 1.0. The AOCL host runtime conforms with the OpenCL platform layer and application programming interface (API), with clarifications and exceptions.

The following sections outline the support statuses of the OpenCL features described in the *OpenCL Specification version 1.0*.

Related Information

OpenCL Specification version 1.0

OpenCL Programming Language Implementation

OpenCL is based on C99 with some limitations. Section 6 of the *OpenCL Specification version 1.0* describes the OpenCL C programming language. The Altera Software Development Kit (SDK) for OpenCL (AOCL) conforms with the OpenCL C programming language with clarifications and exceptions. The table below summarizes the support statuses of the features in the OpenCL programming language implementation.

Attention: The support status "•" means that a clarification for the supported feature is available in the Notes column. The support status "o" means that the feature is supported with exceptions identified in the Notes column. A feature that is not supported by the AOCL is identified with an "X". OpenCL programming language implementations that are supported with no additional clarifications are not shown.

Section	Feature	Support Status	Notes
	Built-in Scalar Data Types		
	double precision float	0	Preliminary support for all double precision float built-in scalar data type. This feature might not conform with the OpenCL Specification version 1.0.
6.1.1	half precision float	X	Support for scalar addition, subtraction and multiplication. Support for conversions to and from single-precision floating point. This feature might not conform with the OpenCL Specification version 1.0.

ISO 9001:2008 Registered

Section	Feature	Support Status	Notes	
6.1.2	Built-in Vector Data Types	0	Preliminary support for vectors with three elements. Three-element vector support is a supplement to the OpenCL Specification version 1.0.	
6.1.3	Built-in Data Types	X		
6.1.4	Reserved Data Types	X		
6.1.5	Alignment of Types	•	All scalar and vector types are aligned as required (vectors with three elements are aligned as if they had four elements).	
6.2.1	Implicit Conversions	•	Refer to Section 6.2.6: <i>Usual Arithmetic Conversions</i> in the <i>OpenCL Specification version 1.2</i> for an important clarification of implicit conversions between scalar and vector types.	
6.2.2	Explicit Casts	•	The AOCL allows scalar data casts to a vector with a different element type.	
6.5	Address Space Qualifiers	0	Function scopeconstant variables are not supported.	
6.6	Image Access Qualifiers	X		
6.7	Function Qualifiers			
6.7.2	Optional Attribute Qualifiers	•	Refer to the Altera SDK for OpenCL Best Practices Guide for tips on using reqd_work_group_size to improve kernel performance.	
			The AOCL parses but ignores the vec_type_hint and work_group_size_hint attribute qualifiers.	
	Preprocessor Directives and Macros			
	#pragma directive: #pragma unroll	•	The Altera Offline Compiler (AOC) supports only #pragma unroll. You may assign an integer argument to the unroll directive to control the extent of loop unrolling.	
			For example, #pragma unroll 4 unrolls four iterations of a loop.	
6.9			By default, an unroll directive with no unroll factor causes the AOC to attempt to unroll the loop fully.	
			Refer to the Altera SDK for OpenCL Best Practices Guide for tips on using #pragma unroll to improve kernel performance.	
	ENDIAN_LITTLE defined to be value 1	•	The target FPGA is little-endian.	
	IMAGE_SUPPORT	X	IMAGE_SUPPORT is undefined; the AOCL does not support images.	

Section	Feature	Support Status	Notes
6.10	Attribute Qualifiers—The AOC parses attribute qualifiers as follows:		
6.10.2	Specifying Attributes of Functions—Structure-type kernel arguments	X	Convert structure arguments to a pointer to a structure in global memory.
6.10.3	Specifying Attributes of Variables—endian	X	
6.10.4	Specifying Attributes of Blocks and Control-Flow-Statements	X	
6.10.5	Extending Attribute Qualifiers	•	The AOC can parse attributes on various syntactic structures. It reserves some attribute names for its own internal use.
			Refer to the <i>Altera SDK for OpenCL Best Practices Guide</i> for tips on how to optimize kernel performance using these kernel attributes.
	Math Functions		
6.11.2	built-in math functions	0	Preliminary support for built-in math functions for double precision float. These functions might not conform with the OpenCL Specification version 1.0.
V.12.12	built-in half_ and native_ math functions	0	Preliminary support for built-in half_and native_math functions for double precision float. These functions might not conform with the OpenCL Specification version 1.0.
6.11.5	Geometric Functions	0	Preliminary support for built-in geometric functions for double precision float. These functions might not conform with the OpenCL Specification version 1.0.
			Refer to <i>Argument Types for Built-in Geometric Functions</i> for a list of built-in geometric functions supported by the AOCL.
6.11.8	Image Read and Write Functions	X	
6.11.9	Synchronization Functions—the barrier synchronization function	0	Clarifications and exceptions: If a kernel specifies the reqd_work_group_size or max_work_group_size attribute, barrier supports the corresponding number of work-items. If neither attribute is specified, a barrier is instantiated with a default limit of 256 work-items. The work-item limit is the maximum supported work-group size for the kernel; this limit is enforced by the runtime.

Section	Feature	Support Status	Notes		
6.11.11	Async Copies from Global to	0	The implementation is naive:		
	Local Memory, Local to Global Memory, and Prefetch		Work-item (0,0,0) performs the copy and the wait_group_events is implemented as a barrier.		
			If a kernel specifies the reqd_work_group_size or max_work_group_size attribute, wait_group_events supports the corresponding number of work-items.		
			If neither attribute is specified, wait_group_events is instantiated with a default limit of 256 work-items.		
	Additional built-in vector functions from the <i>OpenCL Specification version 1.2</i> Section 6.12.12: <i>Miscellaneous Vector Functions</i> :				
	vec_step	•			
	shuffle	•			
	shuffle2	•			
	OpenCL Specification version 1.2 Section 6.12.13: printf		Preliminary support. This feature might not conform with the OpenCL Specification version 1.0. See below for details.		

Section	Feature	Support Status	Notes
		Status	

The printf function in OpenCL has syntax and features similar to the printf function in C99, with a few exceptions. For details, refer to the *OpenCL Specification version 1.2*.

To use a printf function, there are no requirements for special compilation steps, buffers, or flags. You can compile kernels that include printf instructions with the usual acc command.

During kernel execution, printf data is stored in a global printf buffer that the AOC allocates automatically. The size of this buffer is 64 kB; the total size of data arguments to a printf call should not exceed this size. When kernel execution completes, the contents of the printf buffer are printed to standard output.

Buffer overflows are handled seamlessly; printf instructions can be executed an unlimited number of times. However, if the printf buffer overflows, kernel pipeline execution stalls until the host reads the buffer and prints the buffer contents.

Because printf functions store their data into a global memory buffer, the performance of your kernel will drop if it includes such functions.

There are no usage limitations on printf functions. You can use printf instructions inside if-then-else statements, loops, etc. A kernel can contain multiple printf instructions executed by multiple workitems.

Format string arguments and literal string arguments of printf calls are transferred to the host system from the FPGA using a special memory region. This memory region can overflow if the total size of the printf string arguments is large (3000 characters or less is usually safe in a typical OpenCL application). If there is an overflow, the error message cannot parse auto-discovery string at byte offset 4096 is printed during host program execution.

Output from printf is never intermixed, even though work-items may execute printf functions concurrently. However, the order of concurrent printf execution is not guaranteed. In other words, printf outputs might not appear in program order if the printf instructions are in concurrent datapaths.

OpenCL Programming Language Restrictions

The Altera Software Development Kit (SDK) for OpenCL (AOCL) conforms with the OpenCL Specification restrictions on specific programming language features, as described in section 6.8 of the *OpenCL Specification version 1.0*.

Warning: The Altera Offline Compiler (AOC) does not enforce restrictions on certain disallowed programming language features. Ensure that your kernel code does not contain features that the OpenCL Specification version 1.0 does not support.

Feature	Support Status	Notes
pointer assignments between address spaces	•	Arguments tokernel functions declared in a program that are pointers must be declared with theglobal, constant, orlocal qualifier.
		The AOC enforces the OpenCL restriction against pointer assignments between address spaces.
pointers to functions	X	The AOC does not enforce this restriction.
structure-type kernel arguments	X	Convert structure arguments to a pointer to a structure in global memory.
images	X	The AOCL does not support images.
bit fields	X	The AOC does not enforce this restriction.
variable length arrays and structures	X	
variable macros and functions	X	
C99 headers	X	
extern, static, auto, and register storage-class specifiers	X	The AOC does not enforce this restriction.
predefined identifiers	•	Use the -D option of the aoc command to provide preprocessor symbol definitions in your kernel code.
recursion	X	The AOC does not enforce this restriction.
irreducible control flow	X	The AOC does not enforce this restriction.
writes to memory of built-in types less than 32 bits in size	0	Store operations less than 32 bits in size might result in lower memory performance.
declaration of arguments to kernel functions of type event_t	X	The AOC does not enforce this restriction.
elements of a struct or a union belonging to different address spaces	X	The AOC does not enforce this restriction. Warning: Assigning elements of a struct or a union to different address spaces might cause a fatal error.

Argument Types for Built-in Geometric Functions

The Altera Software Development Kit (SDK) for OpenCL (AOCL) supports scalar and vector argument built-in geometric functions with certain limitations.

Function	Argument Type		
runction	float	double	
cross		•	
dot		•	
distance		•	
length		•	
normalize		•	
fast_distance		_	
fast_length		_	
fast_normalize		_	

Numerical Compliance Implementation

Section 7 of the OpenCL Specification version 1.0 describes features of the C99 and IEEE 754 standards that OpenCL-compliant devices must support. The Altera Software Development Kit (SDK) for OpenCL (AOCL) operates on 32-bit and 64-bit floating-point values in IEEE Standard 754-2008 format, but not all floating-point operators have been implemented.

The table below summarizes the implementation statuses of the floating-point operators:

Section	Feature	Support Status	Notes
7.1	Rounding Modes	0	Conversion between integer and single and half precision floating-point types support all rounding modes. Conversions between integer and double precision floating-point types support all rounding modes on a preliminary basis. This feature might not conform with the OpenCL Specification version 1.0.
7.2	INF, NaN and Denormalized Numbers	0	Infinity (INF) and Not a Number (NaN) results for single precision operations are generated in a manner that conforms with the OpenCL Specification version 1.0. Most operations that handle denormalized numbers are flushed prior to and after a floating-point operation. Preliminary support for double precision floating-point operation. This feature might not conform with the OpenCL Specification version 1.0.
7.3	Floating-Point Exceptions	X	

Section	Feature	Support Status	Notes
7.4	Relative Error as ULPs	0	Single precision floating-point operations conform with the numerical accuracy requirements for an embedded profile of the OpenCL Specification version 1.0. Preliminary support for double precision floating-point operation. This feature might not conform with the OpenCL Specification version 1.0.
7.5	Edge Case Behavior	•	

Image Addressing and Filtering Implementation

The Altera Software Development Kit (SDK) for OpenCL (AOCL) does not support image addressing and filtering. The AOCL does not support images.

Atomic Functions

Section 9 of the *OpenCL Specification version 1.0* describes a list of optional features that some OpenCL implementations might support. The Altera Software Development Kit (SDK) for OpenCL (AOCL) supports atomic functions conditionally.

- Section 9.5: Atomic Functions for 32-bit Integers—The AOCL supports all 32-bit global and local memory atomic functions. The AOCL also supports 32-bit atomic functions described in Section 6.11.11 of the OpenCL Specification version 1.1 and Section 6.12.11 of the OpenCL Specification version 1.2.
 - The AOCL does not support 64-bit atomic functions described in Section 9.7 of the *OpenCL Specification version 1.0*.

Attention: The use of atomic functions might lower the performance of your design. The operating frequency of the hardware might decrease further if you implement more than one type of atomic functions (for example, atomic_add and atomic_sub) in the kernel.

Embedded Profile Implementation

Section 10 of the *OpenCL Specification version 1.0* describes the OpenCL embedded profile. The Altera Software Development Kit (SDK) for OpenCL (AOCL) conforms with the OpenCL embedded profile with clarifications and exceptions.

The table below summarizes the clarifications and exceptions to the OpenCL embedded profile:

Clause	Feature	Support Status	Notes
1	64-bit integers	•	
2	3D images	X	The AOCL does not support images.

Clause	Feature	Support Status	Notes
3	Create 2D and 3D images with image_channel_data_type values	X	The AOCL does not support images.
4	Samplers	X	
5	Rounding modes	•	The default rounding mode for CL_DEVICE_SINGLE_FP_CONFIG is CL_FP_ROUND_TO_NEAREST.
6	Restrictions listed for single precision basic floating-point operations	X	
7	half type	X	This clause of the OpenCL Specification version 1.0 does not apply to the AOCL.
8	Error bounds listed for conversions from CL_UNORM_INT8, CL_SNORM_INT8, CL_UNORM_INT16 and CL_SNORM_INT16 to float	•	Refer to the table below for a list of allocation limits.

AOCL Allocation Limits

Item	Limit
Maximum number of contexts	Limited only by host memory size
Maximum number of queues	70
	Attention: Each context uses two queues for system purposes.
Maximum number of program objects per context	20
Maximum number of even objects per context	Limited only by host memory size
Maximum number of dependencies between events within a context	1000
Maximum number of event dependencies per command	20
Maximum number of concurrently running kernels	The total number of queues
Maximum number of enqueued kernels	1000
Maximum number of kernels per FPGA device	64
Maximum number of arguments per kernel	128
Maximum total size of kernel arguments	256 bytes per kernel

Document Revision History

Table A-1: Document Revision History of Appendix A: Support Statuses of OpenCL Features

Date	Document Version	Changes
December 2014	14.1.0	• In <i>AOCL Allocation Limits</i> , updated the maximum number of kernels per FPGA device from 32 to 64.
June 2014	14.0.0	 Updated the following AOCL allocation limits: Maximum number of contexts Maximum number of queues Maximum number of even objects per context
December 2013	13.1.1	 Modified support status designations in <i>Appendix: Support Statuses of OpenCL Features</i>. Removed information on OpenCL programming language restrictions from the section <i>OpenCL Programming Language Implementation</i>, and presented the information in a new section titled <i>OpenCL Programming Language Restrictions</i>.
November 2013	13.1.0	Maintenance release.
June 2013	13.0 SP1.0	 Renamed <i>Optional Extensions</i> to <i>Atomic Functions</i>, and updated its content. Removed <i>Platform Layer and Runtime Implementation</i>.
May 2013	13.0.1	Maintenance release.
May 2013	13.0.0	Added updated information on allocation limits and OpenCL language support.
November 2012	12.1.0	Initial release.
