

ST10F272B ST10F272E

16-bit MCU with 256 Kbyte Flash memory and 12/20 Kbyte RAM

Datasheet — production data

Features

- 16-bit CPU with DSP functions
 - 31.25ns instruction cycle time at 64MHz max CPU clock
 - Multiply/accumulate unit (MAC) 16 x 16-bit multiplication, 40-bit accumulator
 - Enhanced boolean bit manipulations
 - Single-cycle context switching support
- On-chip memories
 - 256 Kbyte Flash memory (32-bit fetch)
 - Single voltage Flash memories with erase/program controller and 100K erasing/programming cycles.
 - Up to 16 Mbyte linear address space for code and data (5 Mbytes with CAN or I²C)
 - 2 Kbyte internal RAM (IRAM)
 - 10/18 Kbyte extension RAM (XRAM)
 - Programmable external bus configuration & characteristics for different address ranges
 - Five programmable chip-select signals
 - Hold-acknowledge bus arbitration support
- Interrupt
 - 8-channel peripheral event controller for single cycle interrupt driven data transfer
 - 16-priority-level interrupt system with 56 sources, sampling rate down to 15.6ns
- Timers
 - Two multi-functional general purpose timer units with 5 timers
- Two 16-channel capture / compare units
- 4-channel PWM unit + 4-channel XPWM
- A/D converter
 - 24-channel 10-bit
 - 3 µs minimum conversion time
- Serial channels
 - Two synch. / asynch. serial channels
 - Two high-speed synchronous channels
 - One I²C standard interface
- 2 CAN 2.0B interfaces operating on 1 or 2 CAN busses (64 or 2x32 message, C-CAN version)
- Fail-safe protection
 - Programmable watchdog timer
 - Oscillator watchdog
- On-chip bootstrap loader
- Clock generation
 - On-chip PLL with 4 to 8 MHz oscillator
 - Direct or prescaled clock input
- Real time clock and 32 kHz on-chip oscillator
- Up to 111 general purpose I/O lines
 - Individually programmable as input, output or special function
 - Programmable threshold (hysteresis)
- Idle, power down and stand-by modes
- Single voltage supply: 5V ±10%

1 Introduction

1.1 Description

The ST10F272B / E device is a STMicroelectronics ST10 family of 16-bit single-chip CMOS microcontrollers.

The ST10F272B / E combines high CPU performance (up to 20 million instructions per second) with high peripheral functionality and enhanced I/O capabilities. It also provides on-chip high-speed single voltage Flash memory, on-chip high-speed RAM, and clock generation via PLL.

The ST10F272B / E is processed in 0.18mm CMOS technology. The part is supplied with a single 5 V supply and I/Os work at 5 V.

1.2 Special characteristics

The ST10F272B and ST10F272E devices are derivatives of the STMicroelectronics ST10 family of 16-bit single-chip CMOS microcontrollers.

These two derivatives slightly differ on the available RAM size and Analog Channel Input number. These points will be highlighted in the corresponding chapters.

For all information that is common to the 2 derivatives, the generic ST10F272 name is used.

The ST10F272 combines high CPU performance (up to 32 million instructions per second) with high peripheral functionality and enhanced I/O-capabilities. It also provides on-chip high-speed single voltage Flash memory, on-chip high-speed RAM, and clock generation via PLL.

ST10F272 is processed in 0.18mm CMOS technology. The MCU core and the logic is supplied with a 5V to 1.8V on-chip voltage regulator. The part is supplied with a single 5V supply and I/Os work at 5V.

The device is upward compatible with the ST10F269 device, with the following set of differences:

Flash control interface is now based on STMicroelectronics third generation of stand-alone Flash memories (M29F400 series), with an embedded Program/Erase Controller. This completely frees up the CPU during programming or erasing the Flash.

Only one supply pin (ex DC1 in ST10F269, renamed into V18) on the QFP144 package is used for decoupling the internally generated 1.8V core logic supply. Do not connect this pin to 5.0V external supply. Instead, this pin should be connected to a decoupling capacitor (ceramic type, typical value 10nF, maximum value 100nF).

The AC and DC parameters are modified due to a difference in the maximum CPU frequency.

A new VDD pin replaces DC2 of ST10F269.

EA pin assumes a new alternate functionality: it is also used to provide a dedicated power supply (see VSTBY) to maintain biased a portion of the XRAM (16Kbytes) when the main Power Supply of the device (VDD and consequently the internally generated V18) is turned off for low power mode, allowing data retention. VSTBY voltage shall be in the range 4.5-5.5 Volt, and a dedicated embedded low power voltage regulator is in charge to provide the

1.8V for the RAM, the low-voltage section of the 32kHz oscillator and the Real Time Clock module when not disabled. It is allowed to exceed the upper limit up to 6V for a very short period of time during the global life of the device, and exceed the lower limit down to 4V when RTC and 32kHz on-chip oscillator are not used.

A second SSC mapped on the XBUS is added (SSC of ST10F269 becomes here SSC0, while the new one is referred as XSSC or simply SSC1). Note that some restrictions and functional differences due to the XBUS peculiarities are present between the classic SSC, and the new XSSC.

A second ASC mapped on the XBUS is added (ASC0 of ST10F269 remains ASC0, while the new one is referred as XASC or simply as ASC1). Note that some restrictions and functional differences due to the XBUS peculiarities are present between the classic ASC, and the new XASC.

A second PWM mapped on the XBUS is added (PWM of ST10F269 becomes here PWM0, while the new one is referred as XPWM or simply as PWM1). Note that some restrictions and functional differences due to the XBUS peculiarities are present between the classic PWM, and the new XPWM.

An I2C interface on the XBUS is added (see X-I2C or simply I2C interface).

CLKOUT function can output either the CPU clock (like in ST10F269) or a software programmable prescaled value of the CPU clock.

On-chip RAM memory has been increased (Flash size remained the same).

PLL multiplication factors have been adapted to new frequency range.

A/D Converter is not fully compatible versus ST10F269 (timing and programming model). Formula for the conversion time is still valid, while the sampling phase programming model is different.

Besides, additional 8 channels are available on P1L pins as alternate function: the accuracy reachable with these extra channels is reduced with respect to the standard Port5 channels.

External Memory bus is affected by limitations on maximum speed and maximum capacitance load: ST10F272 is not able to address an external memory at 64MHz with 0 wait states.

XPERCON register bit mapping modified according to new peripherals implementation (not fully compatible with ST10F269).

Bondout chip for emulation (ST10R201) cannot achieve more than 50MHz at room temperature (so no real time emulation possible at maximum speed).

Input section characteristics are different. The threshold programmability is extended to all port pins (additional XPICON register); it is possible to select standard TTL (with up to 400mV of hysteresis) and standard CMOS (with up to 750mV of hysteresis).

Output transition is not programmable.

CAN module is enhanced: ST10F272 implements two C-CAN modules, so the programming model is slightly different. Besides, the possibility to map in parallel the two CAN modules is added (on P4.5/P4.6).

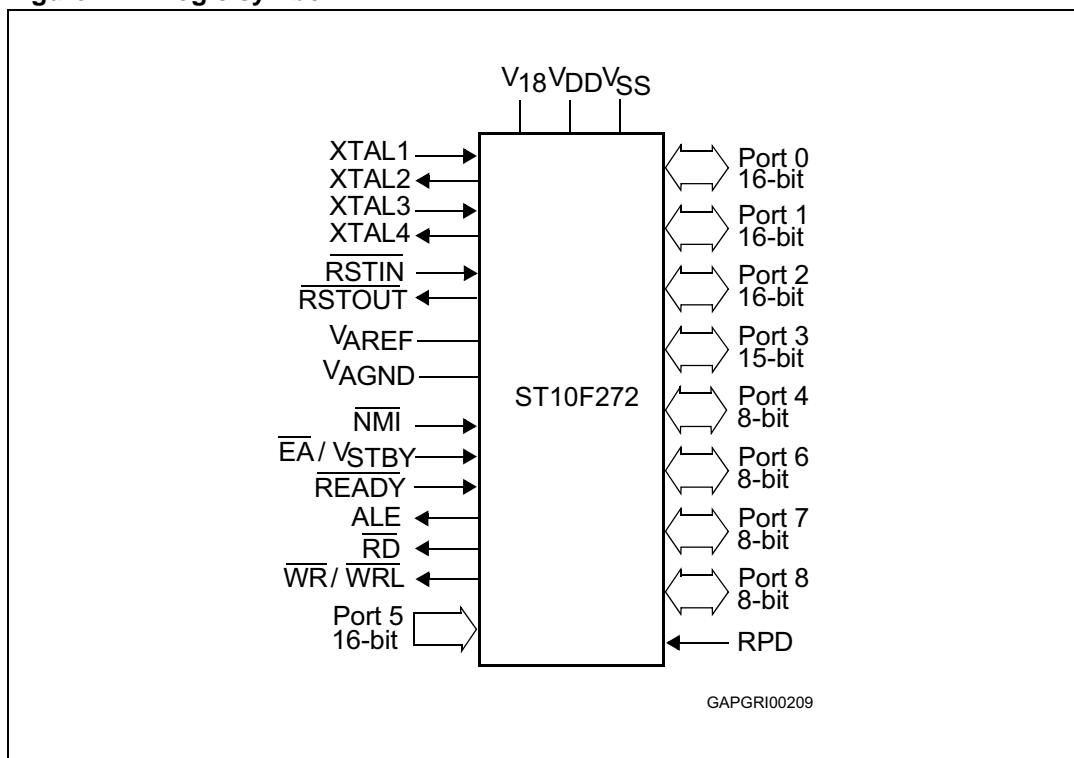

On-chip main oscillator input frequency range has been reshaped, reducing it from 1-25MHz down to 4-8MHz. This is a low power oscillator amplifier, that allows a power consumption reduction when Real Time Clock is running in Power Down mode, using as reference the on-chip main oscillator clock. When this on-chip amplifier is used as reference for Real Time

Clock module, the Power-down consumption is dominated by the consumption of the oscillator amplifier itself.

A second on-chip oscillator amplifier circuit (32kHz) is implemented for low power modes: it can be used to provide the reference to the Real Time Clock counter (either in Power Down or Stand-by mode). Pin XTAL3 and XTAL4 replace a couple of VDD/VSS pins of ST10F269.

Possibility to re-program internal XBUS chip select window characteristics (XRAM2 window) is added.

2 Pin data

Figure 2. Pin configuration (top view)

Table 1. Pin description

| Symbol | Pin | Type | Function | | |
|-------------|-------|------|--|--------------------------|--|
| P6.0 - P6.7 | 1 - 8 | I/O | 8-bit bidirectional I/O port, bit-wise programmable for input or output via direction bit. Programming an I/O pin as input forces the corresponding output driver to high impedance state. Port 6 outputs can be configured as push-pull or open drain drivers. The input threshold of Port 6 is selectable (TTL or CMOS). The following Port 6 pins have alternate functions: | | |
| | 1 | O | P6.0 | $\overline{\text{CS0}}$ | Chip select 0 output |
| | ... | ... | ... | ... | ... |
| | 5 | O | P6.4 | $\overline{\text{CS4}}$ | Chip select 4 output |
| | 6 | I | P6.5 | $\overline{\text{HOLD}}$ | External master hold request input |
| | | I/O | | SCLK1 | SSC1: master clock output / slave clock input |
| | 7 | O | P6.6 | $\overline{\text{HLDA}}$ | Hold acknowledge output |
| | | I/O | | MTSR1 | SSC1: master-transmitter / slave-receiver O/I |
| | 8 | O | P6.7 | $\overline{\text{BREQ}}$ | Bus request output |
| | | I/O | | MRST1 | SSC1: master-receiver / slave-transmitter I/O |
| P8.0 - P8.7 | 9-16 | I/O | 8-bit bidirectional I/O port, bit-wise programmable for input or output via direction bit. Programming an I/O pin as input forces the corresponding output driver to high impedance state. Port 8 outputs can be configured as push-pull or open drain drivers. The input threshold of Port 8 is selectable (TTL or CMOS). The following Port 8 pins have alternate functions: | | |
| | 9 | I/O | P8.0 | CC16IO | CAPCOM2: CC16 capture input / compare output |
| | | O | | XPWM0 | PWM1: channel 0 output |
| | ... | ... | ... | ... | ... |
| | 12 | I/O | P8.3 | CC19IO | CAPCOM2: CC19 capture input / compare output |
| | | O | | XPWM0 | PWM1: channel 3 output |
| | 13 | I/O | P8.4 | CC20IO | CAPCOM2: CC20 capture input / compare output |
| | 14 | I/O | P8.5 | CC21IO | CAPCOM2: CC21 capture input / compare output |
| | 15 | I/O | P8.6 | CC22IO | CAPCOM2: CC22 capture input / compare output |
| | | I/O | | RxD1 | ASC1: Data input (Asynchronous) or I/O (Synchronous) |
| | 16 | I/O | P8.7 | CC23IO | CAPCOM2: CC23 capture input / compare output |
| | | O | | TxD1 | ASC1: Clock / Data output (Asynchronous/Synchronous) |

Table 1. Pin description (continued)

| Symbol | Pin | Type | Function | | |
|------------------------------|----------------|--------|---|--------|---|
| P7.0 - P7.7 | 19-26 | I/O | 8-bit bidirectional I/O port, bit-wise programmable for input or output via direction bit. Programming an I/O pin as input forces the corresponding output driver to high impedance state. Port 7 outputs can be configured as push-pull or open drain drivers. The input threshold of Port 7 is selectable (TTL or CMOS). The following Port 7 pins have alternate functions: | | |
| | 19 | O | P7.0 | POUT0 | PWM0: channel 0 output |
| | ... | ... | ... | ... | ... |
| | 22 | O | P7.3 | POUT3 | PWM0: channel 3 output |
| | 23 | I/O | P7.4 | CC28IO | CAPCOM2: CC28 capture input / compare output |
| | ... | ... | ... | ... | ... |
| | 26 | I/O | P7.7 | CC31IO | CAPCOM2: CC31 capture input / compare output |
| P5.0 - P5.9 P5.10 - P5.15 | 27-36 39-44 | I I | 16-bit input-only port with Schmitt-Trigger characteristics. The pins of Port 5 can be the analog input channels (up to 16) for the A/D converter, where P5.x equals ANx (Analog input channel x), or they are timer inputs. The input threshold of Port 5 is selectable (TTL or CMOS). The following Port 5 pins have alternate functions: | | |
| | 39 | I | P5.10 | T6EUD | GPT2: timer T6 external up/down control input |
| | 40 | I | P5.11 | T5EUD | GPT2: timer T5 external up/down control input |
| | 41 | I | P5.12 | T6IN | GPT2: timer T6 count input |
| | 42 | I | P5.13 | T5IN | GPT2: timer T5 count input |
| | 43 | I | P5.14 | T4EUD | GPT1: timer T4 external up/down control input |
| | 44 | I | P5.15 | T2EUD | GPT1: timer T2 external up/down control input |
| P2.0 - P2.7 P2.8 - P2.15 | 47-54 57-64 | I/O | 16-bit bidirectional I/O port, bit-wise programmable for input or output via direction bit. Programming an I/O pin as input forces the corresponding output driver to high impedance state. Port 2 outputs can be configured as push-pull or open drain drivers. The input threshold of Port 2 is selectable (TTL or CMOS). The following Port 2 pins have alternate functions: | | |
| | 47 | I/O | P2.0 | CC0IO | CAPCOM: CC0 capture input/compare output |
| | ... | ... | ... | ... | ... |
| | 54 | I/O | P2.7 | CC7IO | CAPCOM: CC7 capture input/compare output |
| | 57 | I/O | P2.8 | CC8IO | CAPCOM: CC8 capture input/compare output |
| | | I | | EX0IN | Fast external interrupt 0 input |
| | ... | ... | ... | ... | ... |
| | 64 | I/O | P2.15 | CC15IO | CAPCOM: CC15 capture input/compare output |
| | | I | | EX7IN | Fast external interrupt 7 input |
| | | I | | T7IN | CAPCOM2: timer T7 count input |

Table 1. Pin description (continued)

| Symbol | Pin | Type | Function | | |
|--------------------------------|-------|------|--|----------|--|
| P4.0 –P4.7 | 85-92 | I/O | Port 4 is an 8-bit bidirectional I/O port. It is bit-wise programmable for input or output via direction bit. Programming an I/O pin as input forces the corresponding output driver to high impedance state. The input threshold is selectable (TTL or CMOS). Port 4.4, 4.5, 4.6 and 4.7 outputs can be configured as push-pull or open drain drivers. In case of an external bus configuration, Port 4 can be used to output the segment address lines: | | |
| | 85 | O | P4.0 | A16 | Segment address line |
| | 86 | O | P4.1 | A17 | Segment address line |
| | 87 | O | P4.2 | A18 | Segment address line |
| | 88 | O | P4.3 | A19 | Segment address line |
| | 89 | O | P4.4 | A20 | Segment address line |
| | | I | | CAN2_RxD | CAN2: receive data input |
| | | I/O | | SCL | I ² C Interface: serial clock |
| | 90 | O | P4.5 | A21 | Segment address line |
| | | I | | CAN1_RxD | CAN1: receive data input |
| | | I | | CAN2_RxD | CAN2: receive data input |
| | 91 | O | P4.6 | A22 | Segment address line |
| | | O | | CAN1_TxD | CAN1: transmit data output |
| | | O | | CAN2_TxD | CAN2: transmit data output |
| | 92 | O | P4.7 | A23 | Most significant segment address line |
| | | O | | CAN2_TxD | CAN2: transmit data output |
| | | I/O | | SDA | I ² C Interface: serial data |
| \overline{RD} | 95 | O | External memory read strobe. \overline{RD} is activated for every external instruction or data read access. | | |
| $\overline{WR}/\overline{WRL}$ | 96 | O | External memory write strobe. In \overline{WR} -mode this pin is activated for every external data write access. In \overline{WRL} mode this pin is activated for low byte data write accesses on a 16-bit bus, and for every data write access on an 8-bit bus. See WRCFG in the SYSCON register for mode selection. | | |
| READY/ READY | 97 | I | Ready input. The active level is programmable. When the ready function is enabled, the selected inactive level at this pin, during an external memory access, will force the insertion of waitstate cycles until the pin returns to the selected active level. | | |
| ALE | 98 | O | Address latch enable output. In case of use of external addressing or of multiplexed mode, this signal is the latch command of the address lines. | | |

Table 1. Pin description (continued)

| Symbol | Pin | Type | Function | | | | | | | | | | | | | | | | | | |
|--|-----------------------------|------------|--|-----------------|-------|--------|----------------|---------|---------|----------------|-----|----------|-----------------|-------|--------|----------------|-----------|-----------|----------------|----------|------------|
| \overline{EA} / V_{STBY} | 99 | I | <p>External access enable pin.</p> <p>A low level applied to this pin during and after Reset forces the ST10F272 to start the program from the external memory space. A high level forces ST10F272 to start in the internal memory space. This pin is also used (when Stand-by mode is entered, that is ST10F272 under reset and main V_{DD} turned off) to bias the 32 kHz oscillator amplifier circuit and to provide a reference voltage for the low-power embedded voltage regulator which generates the internal 1.8V supply for the RTC module (when not disabled) and to retain data inside the Stand-by portion of the XRAM (16Kbyte).</p> <p>It can range from 4.5 to 5.5V (6V for a reduced amount of time during the device life, 4.0V when RTC and 32 kHz on-chip oscillator amplifier are turned off). In running mode, this pin can be tied low during reset without affecting 32 kHz oscillator, RTC and XRAM activities, since the presence of a stable V_{DD} guarantees the proper biasing of all those modules.</p> | | | | | | | | | | | | | | | | | | |
| P0L.0 -P0L.7, P0H.0 P0H.1 - P0H.7 | 100-107, 108, 111-117 | I/O | <p>Two 8-bit bidirectional I/O ports P0L and P0H, bit-wise programmable for input or output via direction bit. Programming an I/O pin as input forces the corresponding output driver to high impedance state. The input threshold of Port 0 is selectable (TTL or CMOS).</p> <p>In case of an external bus configuration, PORT0 serves as the address (A) and as the address / data (AD) bus in multiplexed bus modes and as the data (D) bus in demultiplexed bus modes.</p> <p>Demultiplexed bus modes</p> <table><tr><td>Data path width</td><td>8-bit</td><td>16-bit</td></tr><tr><td>P0L.0 – P0L.7:</td><td>D0 – D7</td><td>D0 - D7</td></tr><tr><td>P0H.0 – P0H.7:</td><td>I/O</td><td>D8 - D15</td></tr></table> <p>Multiplexed bus modes</p> <table><tr><td>Data path width</td><td>8-bit</td><td>16-bit</td></tr><tr><td>P0L.0 – P0L.7:</td><td>AD0 – AD7</td><td>AD0 - AD7</td></tr><tr><td>P0H.0 – P0H.7:</td><td>A8 – A15</td><td>AD8 - AD15</td></tr></table> | Data path width | 8-bit | 16-bit | P0L.0 – P0L.7: | D0 – D7 | D0 - D7 | P0H.0 – P0H.7: | I/O | D8 - D15 | Data path width | 8-bit | 16-bit | P0L.0 – P0L.7: | AD0 – AD7 | AD0 - AD7 | P0H.0 – P0H.7: | A8 – A15 | AD8 - AD15 |
| Data path width | 8-bit | 16-bit | | | | | | | | | | | | | | | | | | | |
| P0L.0 – P0L.7: | D0 – D7 | D0 - D7 | | | | | | | | | | | | | | | | | | | |
| P0H.0 – P0H.7: | I/O | D8 - D15 | | | | | | | | | | | | | | | | | | | |
| Data path width | 8-bit | 16-bit | | | | | | | | | | | | | | | | | | | |
| P0L.0 – P0L.7: | AD0 – AD7 | AD0 - AD7 | | | | | | | | | | | | | | | | | | | |
| P0H.0 – P0H.7: | A8 – A15 | AD8 - AD15 | | | | | | | | | | | | | | | | | | | |

Table 1. Pin description (continued)

| Symbol | Pin | Type | Function | | |
|--------------------------------|--------------------|------|---|--|-----------------------------|
| P1L.0 - P1L.7 P1H.0 - P1H.7 | 118-125 128-135 | I/O | Two 8-bit bidirectional I/O ports P1L and P1H, bit-wise programmable for input or output via direction bit. Programming an I/O pin as input forces the corresponding output driver to high impedance state. PORT1 is used as the 16-bit address bus (A) in demultiplexed bus modes: if at least BUSCONx is configured such the demultiplexed mode is selected, the pins of PORT1 are not available for general purpose I/O function. The input threshold of Port 1 is selectable (TTL or CMOS). Only for the ST10F272E – The pins of P1L also serve as the additional (up to 8) analog input channels for the A/D converter, where P1L.x equals ANY (Analog input channel y, where y = x + 16). This additional function have higher priority on demultiplexed bus function. The following PORT1 pins have alternate functions: | | |
| | 132 | I | P1H.4 | CC24IO | CAPCOM2: CC24 capture input |
| | 133 | I | P1H.5 | CC25IO | CAPCOM2: CC25 capture input |
| | 134 | I | P1H.6 | CC26IO | CAPCOM2: CC26 capture input |
| | 135 | I | P1H.7 | CC27IO | CAPCOM2: CC27 capture input |
| XTAL1 | 138 | I | XTAL1 | Main oscillator amplifier circuit and/or external clock input. | |
| XTAL2 | 137 | O | XTAL2 | Main oscillator amplifier circuit output. | |
| | | | To clock the device from an external source, drive XTAL1 while leaving XTAL2 unconnected. Minimum and maximum high / low and rise / fall times specified in the AC Characteristics must be observed. | | |
| XTAL3 | 143 | I | XTAL3 | 32 kHz oscillator amplifier circuit input | |
| XTAL4 | 144 | O | XTAL4 | 32 kHz oscillator amplifier circuit output | |
| | | | When 32 kHz oscillator amplifier is not used, to avoid spurious consumption, XTAL3 shall be tied to ground while XTAL4 shall be left open. Besides, bit OFF32 in RTCCON register shall be set. 32 kHz oscillator can only be driven by an external crystal, and not by a different clock source. | | |
| $\overline{\text{RSTIN}}$ | 140 | I | Reset Input with CMOS Schmitt-Trigger characteristics. A low level at this pin for a specified duration while the oscillator is running resets the ST10F272. An internal pull-up resistor permits power-on reset using only a capacitor connected to V _{SS} . In bidirectional reset mode (enabled by setting bit BDRSTEN in SYSCON register), the $\overline{\text{RSTIN}}$ line is pulled low for the duration of the internal reset sequence. | | |
| $\overline{\text{RSTOUT}}$ | 141 | O | Internal Reset Indication Output. This pin is driven to a low level during hardware, software or watchdog timer reset. $\overline{\text{RSTOUT}}$ remains low until the EINIT (end of initialization) instruction is executed. | | |
| $\overline{\text{NMI}}$ | 142 | I | Non-Maskable Interrupt Input. A high to low transition at this pin causes the CPU to vector to the NMI trap routine. If bit PWDCFG = '0' in SYSCON register, when the PWRDN (power down) instruction is executed, the $\overline{\text{NMI}}$ pin must be low in order to force the ST10F272 to go into power down mode. If $\overline{\text{NMI}}$ is high and PWDCFG = '0', when PWRDN is executed, the part will continue to run in normal mode. If not used, pin $\overline{\text{NMI}}$ should be pulled high externally. | | |
| V _{AREF} | 37 | - | A/D converter reference voltage and analog supply | | |
| V _{AGND} | 38 | - | A/D converter reference and analog ground | | |

Table 1. Pin description (continued)

| Symbol | Pin | Type | Function |
|-----------------|---|------|--|
| RPD | 84 | - | Timing pin for the return from interruptible power down mode and synchronous / asynchronous reset selection. |
| V _{DD} | 17, 46, 72, 82, 93 , 109, 126, 136 | - | Digital supply voltage = + 5V during normal operation, idle and power down modes. It can be turned off when Stand-by RAM mode is selected. |
| V _{SS} | 18, 45, 55, 71, 83, 94, 110, 127, 139 | - | Digital ground |
| V ₁₈ | 56 | - | 1.8V decoupling pin: a decoupling capacitor (typical value of 10nF, max 100nF) must be connected between this pin and nearest V _{SS} pin. |

3 Functional description

The architecture of the ST10F272 combines advantages of both RISC and CISC processors and an advanced peripheral subsystem. The block diagram gives an overview of the different on-chip components and the high bandwidth internal bus structure of the ST10F272.

Figure 3. Block diagram

4 Memory organization

The memory space of the ST10F272 is configured in a unified memory architecture. Code memory, data memory, registers and I/O ports are organized within the same linear address space of 16M Bytes. The entire memory space can be accessed Byte wise or Word wise. Particular portions of the on-chip memory have additionally been made directly bit addressable.

IFLASH: 256K Bytes of on-chip Flash memory. It is divided in 8 blocks (B0F0...B0F7) that constitute the Bank 0. When Bootstrap mode is selected, the Test-Flash Block B0TF (8Kbyte) appears at address 00'0000h: refer to [Section 5: Internal Flash memory](#) for more details on memory mapping in boot mode. The summary of address range for IFLASH is the following:

Table 2. Summary of IFLASH address range

| Blocks | User Mode | Size |
|--------|---------------------|------|
| B0TF | Not visible | 8K |
| B0F0 | 00'0000h - 00'1FFFh | 8K |
| B0F1 | 00'2000h - 00'3FFFh | 8K |
| B0F2 | 00'4000h - 00'5FFFh | 8K |
| B0F3 | 00'6000h - 00'7FFFh | 8K |
| B0F4 | 01'8000h - 01'FFFFh | 32K |
| B0F5 | 02'0000h - 02'FFFFh | 64K |
| B0F6 | 03'0000h - 03'FFFFh | 64K |
| B0F7 | 04'0000h - 04'FFFFh | 64K |

IRAM: 2K Bytes of on-chip internal RAM (dual-port) is provided as a storage for data, system stack, general purpose register banks and code. A register bank is 16 Wordwide (R0 to R15) and / or Bytewise (RL0, RH0, ..., RL7, RH7) general purpose registers group.

XRAM: 8K/16K+2K Bytes of on-chip extension RAM (single port XRAM) is provided as a storage for data, user stack and code.

The XRAM is divided into 2 areas, the first 2K Bytes named XRAM1 and the second 8K/16K Bytes named XRAM2, connected to the internal XBUS and are accessed like an external memory in 16-bit demultiplexed bus-mode without wait state or read/write delay (31.25ns access at 64MHz CPU clock). Byte and Word accesses are allowed.

The XRAM1 address range is 00'E000h - 00'E7FFh if XPEN (bit 2 of SYSCON register), and XRAM1EN (bit 2 of XPERCON register) are set. If XRAM1EN or XPEN is cleared, then any access in the address range 00'E000h - 00'E7FFh will be directed to external memory interface, using the BUSCONx register corresponding to address matching ADDRSELx register.

The XRAM2 address range is the one selected programming XADRS3 register, if XPEN (bit 2 of SYSCON register), and XRAM2EN (bit 3 of XPERCON register) are set. If bit XPEN is cleared, then any access in the address range programmed for XRAM2 will be directed to

external memory interface, using the BUSCONx register corresponding to address matching ADDRSELx register.

After reset the XRAM2 is mapped from address 09'0000h.

XRAM2 represents also the Stand-by RAM, which can be maintained biased through EA / VSTBY pin when main supply VDD is turned off.

As the XRAM appears like external memory, it cannot be used as system stack or as register banks. The XRAM is not provided for single bit storage and therefore is not bit addressable.

ST10F272B XRAM: 8K+2K Bytes of XRAM.

The XRAM1 (2K Bytes) address range is 00'E000h - 00'E7FFh if enabled.

The XRAM2 (8K Bytes) address range is after reset 09'0000h - 09'1FFFh and is mirrored every 16KByte boundary.

ST10F272E XRAM: 16K+2K Bytes of XRAM

The XRAM1 (2K Bytes) address range is 00'E000h - 00'E7FFh if enabled.

The XRAM2 (16K Bytes) address range is after reset 09'0000h - 09'3FFFh and is mirrored every 16KByte boundary.

SFR/ESFR: 1024 Bytes (2 x 512 Bytes) of address space is reserved for the special function register areas. SFRs are Wordwide registers which are used to control and to monitor the function of the different on-chip units.

CAN1: Address range 00'EF00h - 00'EFFh is reserved for the CAN1 Module access. The CAN1 is enabled by setting XPEN bit 2 of the SYSCON register and by setting CAN1EN bit 0 of the XPERCON register. Accesses to the CAN Module use demultiplexed addresses and a 16-bit data bus (only word accesses are possible). Two wait states give an access time of 62.5ns at 64MHz CPU clock. No tri-state wait states are used.

CAN2: Address range 00'EE00h - 00'EEFFh is reserved for the CAN2 Module access. The CAN2 is enabled by setting XPEN bit 2 of the SYSCON register and by setting CAN2EN bit 1 of the new XPERCON register. Accesses to the CAN Module use demultiplexed addresses and a 16-bit data bus (only word accesses are possible). Two wait states give an access time of 62.5ns at 64MHz CPU clock. No tri-state wait states are used.

If one or the two CAN modules are used, Port 4 cannot be programmed to output all 8 segment address lines. Thus, only 4 segment address lines can be used, reducing the external memory space to 5M Bytes (1M Byte per CS line).

RTC: Address range 00'ED00h - 00'EDFFh is reserved for the RTC Module access. The RTC is enabled by setting XPEN bit 2 of the SYSCON register and bit 4 of the XPERCON register. Accesses to the RTC Module use demultiplexed addresses and a 16-bit data bus (only word accesses are possible). Two waitstates give an access time of 62.5ns at 64MHz CPU clock. No tristate waitstate is used.

PWM1: Address range 00'EC00h - 00'ECFFh is reserved for the PWM1 Module access. The PWM1 is enabled by setting XPEN bit 2 of the SYSCON register and bit 6 of the XPERCON register. Accesses to the PWM1 Module use demultiplexed addresses and a 16-bit data bus (only word accesses are possible). Two waitstates give an access time of 62.5ns at 64MHz CPU clock. No tristate waitstate is used. Only word access is allowed.

ASC1: Address range 00'E900h - 00'E9FFh is reserved for the ASC1 Module access. The ASC1 is enabled by setting XPEN bit 2 of the SYSCON register and bit 7 of the XPERCON register. Accesses to the ASC1 Module use demultiplexed addresses and a 16-bit data bus (only word accesses are possible). Two waitstates give an access time of 62.5 ns at 64MHz CPU clock. No tristate waitstate is used.

SSC1: Address range 00'E800h - 00'E8FFh is reserved for the SSC1 Module access. The SSC1 is enabled by setting XPEN bit 2 of the SYSCON register and bit 8 of the XPERCON register. Accesses to the SSC1 Module use demultiplexed addresses and a 16-bit data bus (only word accesses are possible). Two waitstates give an access time of 62.5ns at 64MHz CPU clock. No tristate waitstate is used.

I2C: Address range 00'EA00h - 00'EAFFh is reserved for the I2C Module access. The I2C is enabled by setting XPEN bit 2 of the SYSCON register and bit 9 of the XPERCON register. Accesses to the I2C Module use demultiplexed addresses and a 16-bit data bus (only word accesses are possible). Two waitstates give an access time of 62.5ns at 64MHz CPU clock. No tristate waitstate is used.

X-Miscellaneous: Address range 00'EB00h - 00'EBFFh is reserved for the access to a set of XBUS additional features. They are enabled by setting XPEN bit 2 of the SYSCON register and bit 10 of the XPERCON register. Accesses to this additional features use demultiplexed addresses and a 16-bit data bus (only word accesses are possible). Two waitstates give an access time of 62.5ns at 64MHz CPU clock. No tristate waitstate is used. The following set of features are provided:

- CLKOUT programmable divider
- XBUS interrupt management registers
- ADC multiplexing on P1L register (only for ST10F272E)
- Port1L digital disable register for extra ADC channels
- CAN2 multiplexing on P4.5/P4.6
- CAN1-2 main clock prescaler
- Main Voltage Regulator disable for power-down mode
- TTL / CMOS threshold selection for Port0, Port1, and Port5.

In order to meet the needs of designs where more memory is required than is provided on chip, up to 16M Bytes of external memory can be connected to the microcontroller.

Visibility of XBUS peripherals

In order to keep the ST10F272 compatible with the ST10F168 / ST10F269, the XBUS peripherals can be selected to be visible on the external address / data bus. Different bits for X-peripheral enabling in XPERCON register must be set. If these bits are cleared before the global enabling with XPEN bit in SYSCON register, the corresponding address space, port pins and interrupts are not occupied by the peripherals, thus the peripheral is not visible and not available. Refer to [Chapter 23: Register set on page 116](#).

Figure 4. ST10F272 on-chip memory mapping (ROMEN=1 / XADRS = 800Bh - Reset value)

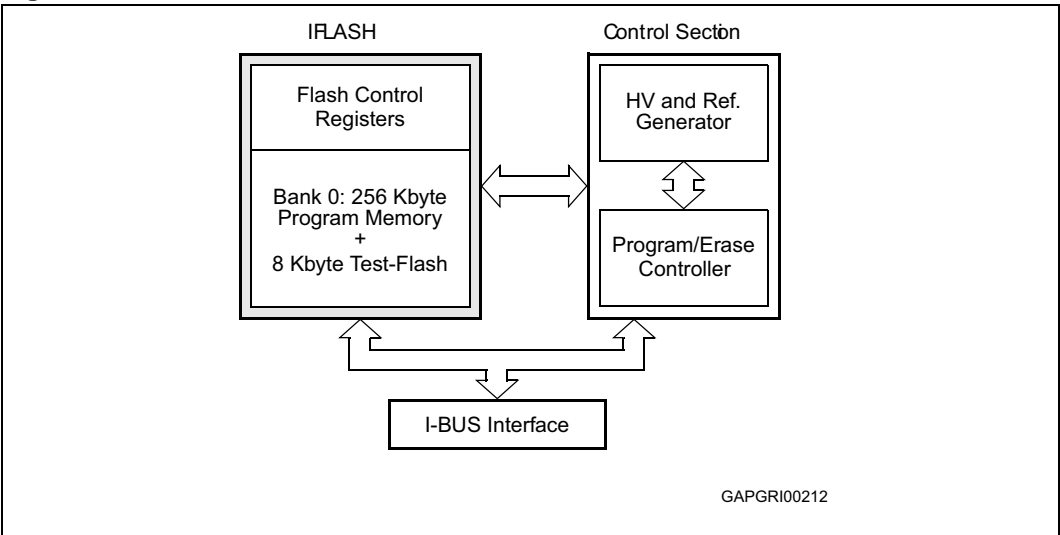

5 Internal Flash memory

5.1 Overview

The on-chip Flash is composed by one matrix module, 256 KBytes wide.
This module is on ST10 Internal bus, so it is called IFLASH

Figure 5. Flash structure

The programming operations of the flash are managed by an embedded Flash Program/Erase Controller (FPEC). The High Voltages needed for Program/Erase operations are internally generated.

The Data bus is 32-bit wide for fetch accesses to IFLASH, while it is 16 bit wide for read accesses to IFLASH. Read/write accesses to IFLASH Control Registers area are 16 bit wide.

5.2 Functional description

5.2.1 Structure

Table 3 shows the Address space reserved to the Flash module.

Table 3. Address space reserved to the Flash module

| Description | Addresses | Size |
|--|------------------------|-----------|
| IFLASH sectors | 0x00 0000 to 0x04 FFFF | 256 Kbyte |
| Reserved IBUS area | 0x05 0000 to 0x07 FFFF | 192 Kbyte |
| Registers and Flash internal reserved area | 0x08 0000 to 0x08 FFFF | 64 Kbyte |

5.2.2 Modules structure

The IFLASH module is composed by a bank (Bank 0) of 256 Kbyte of Program Memory divided in 8 sectors (B0F0...B0F7). Bank 0 contains also a reserved sector named Test-Flash. The Addresses from 0x08 0000 to 0x08 FFFF are reserved for the Control Register Interface and other internal service memory space used by the Flash Program/Erase controller.

The following tables show the memory mapping of the Flash when it is accessed in read mode ([Table 4: Flash modules sectorization \(Read operations\)](#)), and when accessed in write or erase mode ([Table 5: Flash modules sectorization \(Write operations or with ROMS1='1' or BootStrap mode\)](#)): note that with this second mapping, the first four banks are remapped into code segment 1 (same as obtained setting bit ROMS1 in SYSCON register).

Table 4. Flash modules sectorization (Read operations)

| Bank | Description | Addresses | Size | ST10 Bus size |
|------|-----------------------|---------------------------|-------|----------------|
| B0 | Bank 0 Flash 0 (B0F0) | 0x0000 0000 - 0x0000 1FFF | 8 KB | 32-bit (I-BUS) |
| | Bank 0 Flash 1 (B0F1) | 0x0000 2000 - 0x0000 3FFF | 8 KB | |
| | Bank 0 Flash 2 (B0F2) | 0x0000 4000 - 0x0000 5FFF | 8 KB | |
| | Bank 0 Flash 3 (B0F3) | 0x0000 6000 - 0x0000 7FFF | 8 KB | |
| | Bank 0 Flash 4 (B0F4) | 0x0001 8000 - 0x0001 FFFF | 32 KB | |
| | Bank 0 Flash 5 (B0F5) | 0x0002 0000 - 0x0002 FFFF | 64 KB | |
| | Bank 0 Flash 6 (B0F6) | 0x0003 0000 - 0x0003 FFFF | 64 KB | |
| | Bank 0 Flash 7 (B0F7) | 0x0004 0000 - 0x0004 FFFF | 64 KB | |

Table 5. Flash modules sectorization (Write operations or with ROMS1='1' or BootStrap mode)

| Bank | Description | Addresses | Size | ST10 Bus size |
|------|--------------------------|---------------------------|-------|----------------|
| B0 | Bank 0 Test-Flash (B0TF) | 0x0000 0000 - 0x0000 1FFF | 8 KB | 32-bit (I-BUS) |
| | Bank 0 Flash 0 (B0F0) | 0x0001 0000 - 0x0001 1FFF | 8 KB | |
| | Bank 0 Flash 1 (B0F1) | 0x0001 2000 - 0x0001 3FFF | 8 KB | |
| | Bank 0 Flash 2 (B0F2) | 0x0001 4000 - 0x0001 5FFF | 8 KB | |
| | Bank 0 Flash 3 (B0F3) | 0x0001 6000 - 0x0001 7FFF | 8 KB | |
| | Bank 0 Flash 4 (B0F4) | 0x0001 8000 - 0x0001 FFFF | 32 KB | |
| | Bank 0 Flash 5 (B0F5) | 0x0002 0000 - 0x0002 FFFF | 64 KB | |
| | Bank 0 Flash 6 (B0F6) | 0x0003 0000 - 0x0003 FFFF | 64 KB | |
| | Bank 0 Flash 7 (B0F7) | 0x0004 0000 - 0x0004 FFFF | 64 KB | |

[Table 5](#) above refers to the configuration when bit ROMS1 of SYSCON register is set.

When Bootstrap mode is entered:

- Test-Flash is seen and available for code fetches (address 00'0000h)
- User I-Flash is only available for read and write accesses
- Write accesses must be made with addresses starting in segment 1 from 01'0000h, whatever ROMS1 bit in SYSCON value
- Read accesses are made in segment 0 or in segment 1 depending of ROMS1 value.

In Bootstrap mode, by default ROMS1 = 0, so the first 32KBytes of IFlash are mapped in segment 0.

Example:

In default configuration, to program address 0, user must put the value 01'0000h in the FARL and FARH registers, but to verify the content of the address 0 a read to 00'0000h must be performed.

Next [Table 6](#) shows the Control Register interface composition: this set of registers can be addressed by the CPU.

Table 6. Control register interface

| Name | Description | Addresses | Size | Bus size |
|----------|--|---------------------------|--------|----------|
| FCR1-0 | Flash Control Registers 1-0 | 0x0008 0000 - 0x0008 0007 | 8 byte | 16-bit |
| FDR1-0 | Flash Data Registers 1-0 | 0x0008 0008 - 0x0008 000F | 8 byte | |
| FAR | Flash Address Registers | 0x0008 0010 - 0x0008 0013 | 4 byte | |
| FER | Flash Error Register | 0x0008 0014 - 0x0008 0015 | 2 byte | |
| FNVWPIR | Flash Non Volatile Protection I Register | 0x0008 DFB0 - 0x0008 DFB1 | 2 byte | |
| FNVAPR0 | Flash Non Volatile Access Protection Register 0 | 0x0008 DFB8 - 0x0008 DFB9 | 2 byte | |
| FNVAPR1 | Flash Non Volatile Access Protection Register 1 | 0x0008 DFBC - 0x0008 DFBD | 4 byte | |
| XFVTAUR0 | XBus Flash Volatile Temporary Access Unprotection Register 0 | 0x0000 EB50 - 0x0000 EB51 | 2 byte | |

5.2.3 Low power mode

The Flash module is automatically switched off executing PWRDN instruction. The consumption is drastically reduced, but exiting this state can require a long time (t_{PD}).

Recovery time from Power Down mode for the Flash modules is anyway shorter than the main oscillator start-up time. To avoid any problem in restarting to fetch code from the Flash, it is important to size properly the external circuit on RPD pin.

Note: **PWRDN instruction must not be executed while a Flash program/erase operation is in progress.**

5.3 Write operation

The Flash module have one single register interface mapped in the memory space of the IBUS (0x08 0000 to 0x08 0015). All the operations are enabled through four 16-bit control registers: Flash Control Register 1-0 High/Low (FCR1H/L-FCR0H/L). Eight other 16-bit registers are used to store Flash Address and Data for Program operations (FARH/L and FDR1H/L-FDR0H/L) and Write Operation Error flags (FERH/L). All registers are accessible with 8 and 16-bit instructions (since operates in 16-bit mode when in read/ write).

Before accessing the IFlash module (and consequently also the Flash register to be used for program/erasing operations), bit ROMEN in SYSCON register shall be set.

During a Flash write operation any attempt to read the flash itself, that is under modification, will output invalid data (software trap 009Bh). This means that the Flash is not fetchable when a programming operation is active: the write operation commands must be executed from another memory (internal RAM or external memory), as in ST10F269 device. In fact, due to IBUS characteristics, it is not possible to perform a write operation on IFLASH, when fetching code from IFLASH.

Direct addressing is not allowed for write accesses to IFLASH Control Registers.

During a Write operation, when bit LOCK of FCR0 is set, it is forbidden to write into the Flash Control Registers.

Power supply drop

If during a write operation the internal low voltage supply drops below a certain internal voltage threshold, any write operation running is suddenly interrupted and the module is reset to Read mode. At following Power-on, the interrupted Flash write operation must be repeated.

5.4 Registers description

5.4.1 Flash control register 0 low

The Flash Control Register 0 Low (FCR0L) together with the Flash Control Register 0 High (FCR0H) is used to enable and to monitor all the write operations on the IFLASH. The user has no access in write mode to the Test-Flash (B0TF). Besides, Test-Flash block is seen by the user in Bootstrap Mode only.

| FCR0L (0x08 0000) | | | | | | FCR | | | | | | Reset Value: 0000h: | | | |
|-------------------|----|----|----|----|----|-----|---|---|---|---|------|---------------------|------|------|------|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| reserved | | | | | | | | | | | LOCK | res. | res. | BSY0 | res. |
| | | | | | | | | | | | R | | | R | |

Table 7. Flash control register 0 low

| Bit | Function |
|------|---|
| BSY0 | <p>Bank 0 Busy (IFLASH)</p> <p>This bit indicates that a write operation is running on Bank 0 (IFLASH). It is automatically set when bit WMS is set. Setting Protection operation sets bit BSY0 (since protection registers are in this Block). When this bit is set, every read access to Bank 0 will output invalid data (software trap 009Bh), while every write access to the Bank will be ignored. At the end of the write operation or during a Program or Erase Suspend this bit is automatically reset and the Bank returns to read mode. After a Program or Erase Resume this bit is automatically set again.</p> |
| LOCK | <p>Flash Registers Access Locked</p> <p>When this bit is set, it means that the access to the Flash Control Registers FCR0H/-FCR1H/L, FDR0H/L-FDR1H/L, FARH/L and FER is locked by the FPEC: any read access to the registers will output invalid data (software trap 009Bh) and any write access will be ineffective. LOCK bit is automatically set when the Flash bit WMS is set.</p> <p>This is the only bit the user can always access to detect the status of the Flash: once it is found low, the rest of FCR0L and all the other Flash registers are accessible by the user as well.</p> <p>Note that FER content can be read when LOCK is low, but its content is updated only when also BSY0 bit is reset.</p> |

5.4.2 Flash control register 0 high

The Flash Control Register 0 High (FCR0H) together with the Flash Control Register 0 Low (FCR0L) is used to enable and to monitor all the write operations on the IFLASH. The user has no access in write mode to the Test-Flash (B0TF). Besides, Test-Flash block is seen by the user in Bootstrap Mode only.

| FCR0H (0x08 0002) | | | | | FCR | | | | | Reset value: 0000h | | | | | |
|-------------------|------|-----|------|-----|----------|---|-----|----------|---|--------------------|---|---|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| WMS | SUSP | WPG | DWPG | SER | reserved | | SPR | reserved | | | | | | | |
| RW | RW | RW | RW | RW | | | RW | | | | | | | | |

Table 8. Flash control register 0 high

| Bit | Function |
|------|--|
| SPR | <p>Set Protection</p> <p>This bit must be set to select the Set Protection operation. The Set Protection operation allows to program 0s in place of 1s in the Flash Non Volatile Protection Registers. The Flash Address in which to program must be written in the FARH/L registers, while the Flash Data to be programmed must be written in the FDR0H/L before starting the execution by setting bit WMS. A sequence error is flagged by bit SEQR of FER if the address written in FARH/L is not in the range 0x0E8FB0-0x08DFBF. SPR bit is automatically reset at the end of the Set Protection operation.</p> |
| SER | <p>Sector Erase</p> <p>This bit must be set to select the Sector Erase operation in the Flash modules. The Sector Erase operation allows to erase all the Flash locations to value 0xFF. From 1 to all the sectors of the same Bank (excluded Test-Flash for Bank B0) can be selected to be erased through bits BxFy of FCR1H/L registers before starting the execution by setting bit WMS. It is not necessary to pre-program the sectors to 0x00, because this is done automatically. SER bit is automatically reset at the end of the Sector Erase operation.</p> |
| DWPG | <p>Double Word Program</p> <p>This bit must be set to select the Double Word (64 bits) Program operation in the Flash module. The Double Word Program operation allows to program 0s in place of 1s. The Flash Address in which to program (aligned with even words) must be written in the FARH/L registers, while the 2 Flash Data to be programmed must be written in the FDR0H/L registers (even word) and FDR1H/L registers (odd word) before starting the execution by setting bit WMS. DWPG bit is automatically reset at the end of the Double Word Program operation.</p> |
| WPG | <p>Word Program</p> <p>This bit must be set to select the Word (32 bits) Program operation in the Flash module. The Word Program operation allows to program 0s in place of 1s. The Flash Address to be programmed must be written in the FARH/L registers, while the Flash Data to be programmed must be written in the FDR0H/L registers before starting the execution by setting bit WMS. WPG bit is automatically reset at the end of the Word Program operation.</p> |

Table 8. Flash control register 0 high (continued)

| Bit | Function |
|------|--|
| SUSP | <p>Suspend</p> <p>This bit must be set to suspend the current Program (Word or Double Word) or Sector Erase operation in order to read data in one of the Sectors of the Bank under modification or to program data in another Bank. The Suspend operation resets the Flash Bank to normal read mode (automatically resetting bit BSY0). When in Program Suspend, the Flash module accepts only the following operations: Read and Program Resume. When in Erase Suspend the module accepts only the following operations: Read, Erase Resume and Program (Word or Double Word; Program operations cannot be suspended during Erase Suspend). To resume a suspended operation, the WMS bit must be set again, together with the selection bit corresponding to the operation to resume (WPG, DWPG, SER).</p> <p>Note: It is forbidden to start a new Write operation with bit SUSP already set.</p> |
| WMS | <p>Write Mode Start</p> <p>This bit must be set to start every write operation in the Flash module. At the end of the write operation or during a Suspend, this bit is automatically reset. To resume a suspended operation, this bit must be set again. It is forbidden to set this bit if bit ERR or FER is high (the operation is not accepted). It is also forbidden to start a new write (program or erase) operation (by setting WMS high) when bit SUSP of FCR0 is high. Resetting this bit by software has no effect.</p> |

5.4.3 Flash control register 1 low

The Flash Control Register 1 Low (FCR1L), together with Flash Control Register 1 High (FCR1H), is used to select the Sectors to Erase, or during any write operation to monitor the status of each Sector and Bank.

| FCR1L (0x08 0004) | | | | | | | | FCR | | | | | | | | Reset value: 0000h | | | | | | | |
|-------------------|----|----|----|----|----|---|---|------|------|------|------|------|------|------|------|--------------------|--|--|--|--|--|--|--|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | | | | | | | | |
| reserved | | | | | | | | B0F7 | B0F6 | B0F5 | B0F4 | B0F3 | B0F2 | B0F1 | B0F0 | | | | | | | | |
| | | | | | | | | RS | RS | RS | RS | RS | RS | RS | RS | | | | | | | | |

Table 9. Flash control register 1 low

| Bit | Function |
|----------|--|
| B0F(7:0) | <p>Bank 0 IFLASH Sector 9:0 Status</p> <p>These bits must be set during a Sector Erase operation to select the sectors to erase in Bank 0. Besides, during any erase operation, these bits are automatically set and give the status of the 8 sectors of Bank 0 (B0F7-B0F0). The meaning of B0Fy bit for Sector y of Bank 0 is given by the next Table 4 Banks (BxS) and Sectors (BxFy) Status bits meaning. These bits are automatically reset at the end of a Write operation if no errors are detected.</p> |

5.4.4 Flash control register 1 high

The Flash Control Register 1 High (FCR1H), together with Flash Control Register 1 Low (FCR1L), is used to select the Sectors to Erase, or during any write operation to monitor the status of each Sector and Bank.

| FCR1H (0x08 0006) | | | | | | | | FCR | | | | | | | | Reset value: 0000h |
|-------------------|----|----|----|----|----|---|---|-----|----------|---|---|---|---|---|---|--------------------|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | |

| | | | | | | | | RS | | | | | | | | |

Table 10. Flash control register 1 high

| Bit | Function |
|-----|---|
| B0S | Bank 0 Status (IFLASH) During any erase operation, this bit is automatically modified and gives the status of the Bank 0. The meaning of B0S bit is given in the next Table 4 Banks (BxS) and Sectors (BxFy) Status bits meaning. This bit is automatically reset at the end of a erase operation if no errors are detected. |

During any erase operation, this bit is automatically set and gives the status of the Bank 0. The meaning of B0Fy bit for Sector y of Bank 0 is given by the next Table 4 Banks (BxS) and Sectors (BxFy) Status bits meaning. These bits are automatically reset at the end of an erase operation if no errors are detected.

Table 11. Banks (BxS) and sectors (BxFy) status bits meaning

| ERR | SUSP | B0S = 1 meaning | B0Fy = 1 meaning |
|-----|------|---------------------------|---------------------------------------|
| 1 | - | Erase Error in Bank 0 | Erase Error in Sector y of Bank 0 |
| 0 | 1 | Erase Suspended in Bank 0 | Erase Suspended in Sector y of Bank 0 |
| 0 | 0 | Don't care | Don't care |

5.4.5 Flash data register 0 low

The Flash Address Registers (FARH/L) and the Flash Data Registers (FDR1H/L-FDR0H/L) are used during the program operations to store Flash Address in which to program and Data to program.

| FDR0L (0x08 0008) | | | | | | | | FCR | | | | | | | | Reset value: FFFFh |
|-------------------|-------|-------|-------|-------|-------|------|------|------|------|------|------|------|------|------|------|--------------------|

Table 17. Flash address register high

| Bit | Function |
|------------|--|
| ADD(20:16) | Address 20:16 These bits must be written with the Address of the Flash location to program in the following operations: Word Program and Double Word Program. |

5.4.11 Flash error register

Flash Error register, as well as all the other Flash registers, can be properly read only once LOCK bit of register FCR0L is low. Nevertheless, its content is updated when also BSY0 bit is reset as well; for this reason, it is definitively meaningful reading FER register content only when LOCK bit and BSY0 bit are cleared.

| FER (0x8 0014h) | | | | | | | | FCR | | | | Reset value: 0000h | | | |
|-----------------|----|----|----|----|----|---|---|-----|-------|-------|----------|--------------------|------|------|-----|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| reserved | | | | | | | | WPF | RESER | SEQER | reserved | 10ER | PGER | ERER | ERR |
| | | | | | | | | RC | RC | RC | | RC | RC | RC | RC |

Table 18. Flash error register

| Bit | Function |
|-------|---|
| ERR | Write Error This bit is automatically set when an error occurs during a Flash write operation or when a bad write operation setup is done. Once the error has been discovered and understood, ERR bit must be software reset. |
| ERER | Erase Error This bit is automatically set when an Erase error occurs during a Flash write operation. This error is due to a real failure of a Flash cell, that can no more be erased. This kind of error is fatal and the sector where it occurred must be discarded. This bit has to be software reset. |
| PGER | Program Error This bit is automatically set when a Program error occurs during a Flash write operation. This error is due to a real failure of a Flash cell, that can no more be programmed. The word where this error occurred must be discarded. This bit has to be software reset. |
| 10ER | 1 over 0 Error This bit is automatically set when trying to program at 1 bits previously set at 0 (this does not happen when programming the Protection bits). This error is not due to a failure of the Flash cell, but only flags that the desired data has not been written. This bit has to be software reset. |
| SEQER | Sequence Error This bit is automatically set when the control registers (FCR1H/L-FCR0H/L, FARH/L, FDR1H/L-FDR0H/L) are not correctly filled to execute a valid Write Operation. In this case no Write Operation is executed. This bit has to be software reset. |
| RESER | Resume Error This bit is automatically set when a suspended Program or Erase operation is not resumed correctly due to a protocol error. In this case the suspended operation is aborted. This bit has to be software reset. |
| WPF | Write Protection Flag This bit is automatically set when trying to program or erase in a sector write protected. In case of multiple Sector Erase, the not protected sectors are erased, while the protected sectors are not erased and bit WPF is set. This bit has to be software reset. |

5.5 Protection strategy

The protection bits are stored in Non Volatile Flash cells inside IFLASH module, that are read once at reset and stored in 4 Volatile registers. Before they are read from the Non Volatile cells, all the available protections are forced active during reset.

The protections can be programmed using the Set Protection operation (see Flash Control Registers paragraph), that can be executed from all the internal or external memories except from the Flash itself.

Two kind of protections are available: write protections to avoid unwanted writings and access protections to avoid piracy. In next paragraphs all different level of protections are shown, and architecture limitations are highlighted as well.

5.5.1 Protection registers

The 4 Non Volatile Protection Registers are one time programmable for the user.

One register (FNWVPIR) is used to store the Write Protection fuses respectively for each sector IFLASH module. The other three Registers (FNVAPR0 and FNVAPR1L/H) are used to store the Access Protection fuses.

5.5.2 Flash non volatile write protection I register

| FNWVPIR (0x08 DFB0) | | | | | | | | NVR | | | | | | | | Reset value: FFFFh | | | | | | | |
|---------------------|----|----|----|----|----|---|---|------|------|------|------|------|------|------|------|--------------------|--|--|--|--|--|--|--|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 | | | | | | | | |

| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| reserved | | | | | | | | | | | | | DBGP | ACCP | |
| | | | | | | | | | | | | | RW | RW | |

Table 20. Flash non volatile access protection register 0

| Bit | Function |
|------|---|
| ACCP | Access Protection This bit, if programmed at 0, disables any access (read/write) to data mapped inside IFlash Module address space, unless the current instruction is fetched from IFlash. |
| DBGP | Debug Protection This bit, if erased at 1, allows to by-pass all the protections using the Debug features through the Test Interface. If programmed at 0, on the contrary, all the debug features, the Test Interface and all the Flash Test Modes are disabled. Even STMicroelectronics will not be able to access the device to run any eventual failure analysis. |

5.5.4 Flash non volatile access protection register 1 low

| FNVAPR1L (0x08 DFBC) | | | | | | | | | | NVR | | Delivery value:: FFFFh | | | |

| | | | | | | | | | | | | | | | TAUB |
| reserved | | | | | | | | | | | | | | | RW |

Table 23. XBus flash volatile temporary access unprotection register

| Bit | Function |
|------|--|
| TAUB | Temporary Access Unprotection bit If this bit is set to 1, the Access Protection is temporary disabled. This bit can be written only executing from IFlash. This fact guarantees that only a code executed in IFlash, can unprotect the IFlash, when it is Access Protected. |

5.5.7 Access protection

The I-Flash module has one level of access protection (access to data both in Reading and Writing): if bit ACCP of FNVAPR0 is programmed at 0 and bit TAUB in XFVTAUR0 is set at 0, the I-Flash module becomes access protected: data in the I-Flash module can be read only if the current execution is from the I-Flash module itself.

To enable Access Protection, the following sequence of operations is recommended:

- execution from external memory or internal Rams
- program TAUB bit at 1 in XFVTAUR0 register
- program ACCP bit in FNVAPR0 to 0 using Set Protection operation
- program TAUB bit at 0 in XFVTAUR0 register
- Access Protection is active when both ACCP bit and TAUB bit are set to 0.

Protection can be permanently disabled by programming bit PDS0 of FNVAPR1H, in order to analyze rejects. Protection can be permanently enabled again by programming bit PEN0 of FNVAPR1L. The action to disable and enable again Access Protections in a permanent way can be executed a maximum of 16 times. To execute the above described operations,

the Flash has to be temporary unprotected (See [Section 5.5.9: Temporary unprotection](#)).

Trying to write into the access protected Flash from internal RAM or external memories is unsuccessful. Trying to read into the access protected Flash from internal RAM or external memories will output a dummy data (software trap 0x009Bh).

When the Flash module is protected in access, also the data access through PEC of a peripheral is forbidden. To read/write data in PEC mode from/to a protected Bank, first it is necessary to temporary unprotect the Flash module.

In [Table 24](#) there is a summary of all levels of possible Access protection is reported: in particular, supposing to enable all possible access protections, when fetching from a memory as listed in the first column, what is possible and what is not possible to do (see column headers) is shown in the table.

Table 24. Summary of access protection level

| | Read IFLASH / Jump to IFLASH | Read XRAMS or Ext Mem / Jump to XRAM or Ext Mem | Read FLASH Registers | Write FLASH Registers |
|----------------------------------|---------------------------------|---|-------------------------|--------------------------|
| Fetching from IFLASH | Yes / Yes | Yes / Yes | Yes | No |
| Fetching from IRAM | No / Yes | Yes / Yes | Yes | No |
| Fetching from XRAM | No / Yes | Yes / Yes | Yes | No |
| Fetching from External Memory | No / Yes | Yes / Yes | Yes | No |

When the Access Protection is enabled, Flash registers can not be written, so no program/erase operation can be run on I-Flash. To enable the access to registers again, the Temporary Access Unprotection procedure has to be followed (see [Section 5.5.9](#)).

5.5.8 Write protection

The Flash modules have one level of Write Protections: each Sector of each Bank of each Flash Module can be Software Write Protected by programming at 0 the related bit WOPx in FNVWPIRL register.

5.5.9 Temporary unprotection

Bits WOPx of FNVWPIRL can be temporary unprotected by executing the Set Protection operation and by writing 1 into these bits.

To restore the write protection bits it is necessary to reset the microcontroller or to execute a Set Protection operation and write 0 into the desired bits.

In reality, when a temporary write unprotection operation is executed, the corresponding volatile register is written to 1, while the non volatile registers bits previously written to 0 (for a protection set operation), will continue to maintain the 0. For this reason, the User software must be in charge to track the current write protection status (for instance using a specific RAM area), it is not possible to deduce it by reading the non volatile register content (a temporary unprotection cannot be detected).

To temporary unprotect the Flash when the Access Protection is active, it is necessary to set at 1 the bit TAUB in XFVTAUR0. This bit can be write at 1, only executing from Flash: in this way only an instruction executed from Flash can unprotect the Flash itself.

To restore the Access Protection, it is necessary to reset the microcontroller or to write at 0 the bit TAUB in XFVTAUR0.

5.6 Write operation examples

In the following, examples for each kind of Flash write operation are presented.

Note: The write operation commands must be executed from another memory (internal RAM or external memory), as in ST10F269 device. In fact, due to IBus characteristics, it is not possible to perform write operation in Flash while fetching code from Flash.

Moreover, direct addressing is not allowed for write accesses to IFlash control registers. This means that both address and data for a writing operation must be loaded in one of ST10 GPR register (R0...R15).

Write operation on IBus registers is 16 bit wide.

Example of indirect addressing mode

```
MOV  RWm, #ADDRESS;    /*Load Add in RWm*/
MOV  RWn, #DATA;        /*Load Data in RWn*/
MOV  [RWm], RWn;        /*Indirect addressing*/
```

Word program

Example: 32-bit Word Program of data 0xAAAAAAAA at address 0x025554

```
FCR0H |= 0x2000;        /*Set WPG in FCR0H*/
FARL  = 0x5554;          /*Load Add in FARL*/
FARH  = 0x0002;          /*Load Add in FARH*/
FDR0L = 0xAAAA;          /*Load Data in FDR0L*/
FDR0H = 0xAAAA;          /*Load Data in FDR0H*/
FCR0H |= 0x8000;        /*Operation start*/
```

Double word program

Example: Double Word Program (64-bit) of data 0x55AA55AA at address 0x035558 and data 0xAA55AA55 at address 0x03555C in IFLASH Module.

```
FCR0H |= 0x1000;        /*Set DWPG/
FARL  = 0x5558;          /*Load Add in FARL*/
FARH  = 0x0003;          /*Load Add in FARH*/
FDR0L = 0x55AA;          /*Load Data in FDR0L*/
FDR0H = 0x55AA;          /*Load Data in FDR0H*/
FDR1L = 0xAA55;          /*Load Data in FDR1L*/
FDR1H = 0xAA55;          /*Load Data in FDR1H*/
FCR0H |= 0x8000;        /*Operation start*/
```

Double Word Program is always performed on the Double Word aligned on a even Word: bit ADD2 of FARL is ignored.

Sector erase

Example: Sector Erase of sectors B0F1 and B0F0 of Bank 0 in IFLASH Module.

```
FCR0H |= 0x0800;        /*Set SER in FCR0H*/
FCR1L |= 0x0003;        /*Set B0F1, B0F0*/
FCR0H |= 0x8000;        /*Operation start*/
```

Suspend and resume

Word Program, Double Word Program, and Sector Erase operations can be suspended in the following way:

```
FCR0H |= 0x4000; /*Set SUSP in FCR0H*/
```

Then the operation can be resumed in the following way:

```
FCR0H |= 0x0800; /*Set SER in FCR0H*/
FCR0H |= 0x8000; /*Operation resume*/
```

Before resuming a suspended Erase, FCR1H/FCR1L must be read to check if the Erase is already completed (FCR1H = FCR1L = 0x0000 if Erase is complete). Original setup of Select Operation bits in FCR0H/L must be restored before the operation resume, otherwise the operation is aborted and bit RESER of FER is set.

Erase suspend, program and resume

A Sector Erase operation can be suspended in order to program (Word or Double Word) another Sector.

Example: Sector Erase of sector B0F1 of IFLASH Module.

```
FCR0H |= 0x0800; /*Set SER in FCR0H*/
FCR1L |= 0x0002; /*Set B0F1*/
FCR0H |= 0x8000; /*Operation start*/
```

Example: Sector Erase Suspend.

```
FCR0H |= 0x4000; /*Set SUSP in FCR0H*/
do
/*Loop to wait for LOCK=0 and WMS=0*/
{tmp1 = FCR0L;
 tmp2 = FCR0H;
} while ((tmp1 && 0x0010) || (tmp2 && 0x8000));
```

Example: Word Program of data 0x5555AAAA at address 0x045554 in IFLASH module.

```
FCR0H &= 0xBFFF; /*Rst SUSP in FCR0H*/
FCR0H |= 0x2000; /*Set WPG in FCR0H*/
FARL = 0x5554; /*Load Add in FARL*/
FARH = 0x0004; /*Load Add in FARH*/
FDR0L = 0xAAAA; /*Load Data in FDR0L*/
FDR0H = 0x5555; /*Load Data in FDR0H*/
FCR0H |= 0x8000; /*Operation start*/
```

Once the Program operation is finished, the Erase operation can be resumed in the following way:

```
FCR0H |= 0x0800; /*Set SER in FCR0H*/
FCR0H |= 0x8000; /*Operation resume*/
```

Notice that during the Program Operation in Erase suspend, bits SER and SUSP are low. A Word or Double Word Program during Erase Suspend cannot be suspended.

In summary:

A Sector Erase can be suspended by setting SUSP bit.

- To perform a Word Program operation during Erase Suspend, firstly bits SUSP and SER must be reset, then bit WPG and WMS can be set.
- To resume the Sector Erase operation bit SER must be set again.
- In any case it is forbidden to start any write operation with SUSP bit already set.

Set protection

Example 1: Enable Write Protection of sectors B0F3-0 of Bank 0 in IFLASH module.

```
FCR0H  |= 0x0100;      /*Set SPR in FCR0H*/
FARL    = 0xDFB4;      /*Load Add of register FNVWPIR in FARL*/
FARH    = 0x0008;      /*Load Add of register FNVWPIR in FARH*/
FDR0L   = 0xFFFF0;     /*Load Data in FDR0L*/
FDR0H   = 0xFFFF;      /*Load Data in FDR0H*/
FCR0H   |= 0x8000;      /*Operation start*/
```

Example 2: Enable Access and Debug Protection.

```
FCR0H  |= 0x0100;      /*Set SPR in FCR0H*/
FARL    = 0xDFB8;      /*Load Add of register FNVAPR0 in FARL*/
FARH    = 0x0008;      /*Load Add of register FNVAPR0 in FARH*/
FDR0L   = 0xFFFC;      /*Load Data in FDR0L*/
FCR0H   |= 0x8000;      /*Operation start*/
```

Example 3: Disable in a permanent way Access and Debug Protection.

```
XFVTAUR0 = 0x0001;     /*Set TAUB in XFVTAUR0*/
FCR0H    |= 0x0100;     /*Set SPR in FCR0H*/
FARL      = 0xDFBC;     /*Load Add of register FNVAPR1L in FARL*/
FARH      = 0x0008;     /*Load Add of register FNVAPR1L in FARH*/
FDR0L     = 0xFFFE;     /*Load Data in FDR0L for clearing PDS0*/
FCR0H     |= 0x8000;     /*Operation start*/
```

Example 4: Enable again in a permanent way Access and Debug Protection, after having disabled them.

```
XFVTAUR0 = 0x0001;     /*Set TAUB in XFVTAUR0*/
FCR0H    |= 0x0100;     /*Set SPR in FCR0H*/
FARL      = 0xDFBC;     /*Load Add register FNVAPR1H in FARL*/
FARH      = 0x0008;     /*Load Add register FNVAPR1H in FARH*/
FDR0H     = 0xFFFE;     /*Load Data in FDR0H for clearing
PEN0*/
FCR0H     |= 0x8000;     /*Operation start*/
XFVTAUR0 = 0x0000;     /*Reset TAUB in XFVTAUR0*/
```

Disable and re-enable of Access and Debug Protection in a permanent way (as shown by examples 3 and 4) can be done for a maximum of 16 times.

5.7 Write operation summary

In general, each write operation is started through a sequence of 3 steps:

1. The first instruction is used to select the desired operation by setting its corresponding selection bit in the Flash Control Register 0.
2. The second step is the definition of the Address and Data for programming or the Sectors or Banks to erase.
3. The last instruction is used to start the write operation, by setting the start bit WMS in the FCR0.

Once selected, but not yet started, one operation can be canceled by resetting the operation selection bit.

A summary of the available Flash Module Write Operations are shown in the following [Table 25](#).

Table 25. Flash write operations

| Operation | Select bit | Address and data | Start bit |
|------------------------------|------------|---|-----------|
| Word Program (32-bit) | WPG | FARL/FARH FDR0L/FDR0H | WMS |
| Double Word Program (64-bit) | DWPG | FARL/FARH FDR0L/FDR0H FDR1L/FDR1H | WMS |
| Sector Erase | SER | FCR1L/FCR1H | WMS |
| Set Protection | SPR | FDR0L/FDR0H | WMS |
| Program/Erase Suspend | SUSP | None | None |

6 Bootstrap loader

ST10F272 implements Boot capabilities in order to:

- Support bootstrap via UART or bootstrap via CAN for the standard bootstrap.
- Support a Selective Bootstrap Loader, to manage the bootstrap sequence in a different way.

6.1 Selection among user-code, standard or selective bootstrap

The boot modes are triggered with a special combination set on Port0L[5...4]. Those signals, as other configuration signals, are latched on the rising edge of $\overline{\text{RSTIN}}$ pin.

- Decoding of reset configuration (P0L.5 = 1, P0L.4 = 1) will select the normal mode (also called User Mode) and select the user Flash to be mapped from address 00'0000h.
- Decoding of reset configuration (P0L.5 = 1, P0L.4 = 0) will select ST10 standard bootstrap mode (Test-Flash is active and overlaps user Flash for code fetches from address 00'0000h; user Flash is active and available for read accesses).
- Decoding of reset configuration (P0L.5 = 0, P0L.4 = 1) will activate new verifications to select which bootstrap software to execute:
 - if the User mode signature in the User Flash is programmed correctly, then a software reset sequence is selected and the User code is executed;
 - if the User mode signature is not programmed correctly in the user Flash, then the User key location is read again. Its value will determine which communication channel will be enabled for bootstrapping

Table 26. ST10F272 boot mode selection

| P0.5 | P0.4 | ST10 decoding |
|------|------|---|
| 1 | 1 | User Mode: user Flash mapped at 00'0000h |
| 1 | 0 | Standard Bootstrap Loader: User Flash mapped from 00'0000h, code fetches redirected to Test-Flash at 00'0000h |
| 0 | 1 | Selective Boot Mode: User Flash mapped from 00'0000h, code fetches redirected to Test-Flash at 00'0000h (different sequence execution in respect of Standard Bootstrap Loader) |
| 0 | 0 | Reserved |

6.2 Standard bootstrap loader

After entering the standard BSL mode and the respective initialization, the ST10F272 scans the RxD0 line and the CAN1_RxD line to receive either a valid dominant bit from CAN interface, or a start condition from UART line.

Start condition on UART RxD: ST10F272 starts standard bootstrap loader. This bootstrap loader is identical to other ST10 devices (example: ST10F269, ST10F168).

Valid dominant bit on CAN1 RxD: ST10F272 start bootstrapping via CAN1.

6.3 Alternate and selective boot mode (ABM and SBM)

6.3.1 Activation of the ABM and SBM

Alternate boot is activated with the combination '01' on Port0L[5..4] at the rising edge of RSTIN.

6.3.2 User mode signature integrity check

The behavior of the Selective Boot Mode is based on the computing of a signature between the content of 2 memory locations and a comparison with a reference signature. This requires that users who use Selective Boot have reserved and programmed the Flash memory locations.

6.3.3 Selective boot mode

When the user signature is not correct, instead of executing the Standard Bootstrap Loader (triggered by P0L.4 low at reset), additional check is made.

Depending on the value at the User key location, following behavior will occur:

- A jump is performed to the Standard Bootstrap Loader
- Only UART is enabled for bootstrapping
- Only CAN1 is enabled for bootstrapping
- The device enters an infinite loop.

7 Central processing unit (CPU)

The CPU includes a 4-stage instruction pipeline, a 16-bit arithmetic and logic unit (ALU) and dedicated SFRs. Additional hardware has been added for a separate multiply and divide unit, a bit-mask generator and a barrel shifter.

Most of the ST10F272's instructions can be executed in one instruction cycle which requires 31.25ns at 64 MHz CPU clock. For example, shift and rotate instructions are processed in one instruction cycle independent of the number of bits to be shifted.

Multiple-cycle instructions have been optimized: branches are carried out in 2 cycles, 16 x 16-bit multiplication in 5 cycles and a 32/16-bit division in 10 cycles.

The jump cache reduces the execution time of repeatedly performed jumps in a loop, from 2 cycles to 1 cycle.

The CPU uses a bank of 16 word registers to run the current context. This bank of General Purpose Registers (GPR) is physically stored within the on-chip Internal RAM (IRAM) area. A Context Pointer (CP) register determines the base address of the active register bank to be accessed by the CPU.

The number of register banks is only restricted by the available Internal RAM space. For easy parameter passing, a register bank may overlap others.

A system stack of up to 2048 bytes is provided as a storage for temporary data. The system stack is allocated in the on-chip RAM area, and it is accessed by the CPU via the stack pointer (SP) register.

Two separate SFRs, STKOV and STKUN, are implicitly compared against the stack pointer value upon each stack access for the detection of a stack overflow or underflow.

Figure 6. CPU block diagram (MAC Unit not included)

7.1 Multiplier-accumulator unit (MAC)

The MAC co-processor is a specialized co-processor added to the ST10 CPU Core in order to improve the performances of the ST10 Family in signal processing algorithms.

The standard ST10 CPU has been modified to include new addressing capabilities which enable the CPU to supply the new co-processor with up to 2 operands per instruction cycle.

This new co-processor (so-called MAC) contains a fast multiply-accumulate unit and a repeat unit.

The co-processor instructions extend the ST10 CPU instruction set with multiply, multiply-accumulate, 32-bit signed arithmetic operations.

Figure 7. MAC unit architecture

7.2 Instruction set summary

The [Table 27](#) lists the instructions of the ST10F272. The detailed description of each instruction can be found in the “ST10 Family Programming Manual”.

Table 27. Standard instruction set summary

| Mnemonic | Description | Bytes |
|------------------|---|-------|
| ADD(B) | Add word (byte) operands | 2 / 4 |
| ADDC(B) | Add word (byte) operands with Carry | 2 / 4 |
| SUB(B) | Subtract word (byte) operands | 2 / 4 |
| SUBC(B) | Subtract word (byte) operands with Carry | 2 / 4 |
| MUL(U) | (Un)Signed multiply direct GPR by direct GPR (16-16-bit) | 2 |
| DIV(U) | (Un)Signed divide register MDL by direct GPR (16-/16-bit) | 2 |
| DIVL(U) | (Un)Signed long divide reg. MD by direct GPR (32-/16-bit) | 2 |
| CPL(B) | Complement direct word (byte) GPR | 2 |
| NEG(B) | Negate direct word (byte) GPR | 2 |
| AND(B) | Bit-wise AND, (word/byte operands) | 2 / 4 |
| OR(B) | Bit-wise OR, (word/byte operands) | 2 / 4 |
| XOR(B) | Bit-wise XOR, (word/byte operands) | 2 / 4 |
| BCLR | Clear direct bit | 2 |
| BSET | Set direct bit | 2 |
| BMOV(N) | Move (negated) direct bit to direct bit | 4 |
| BAND, BOR, BXOR | AND/OR/XOR direct bit with direct bit | 4 |
| BCMP | Compare direct bit to direct bit | 4 |
| BFLDH/L | Bit-wise modify masked high/low byte of bit-addressable direct word memory with immediate data | 4 |
| CMP(B) | Compare word (byte) operands | 2 / 4 |
| CMPD1/2 | Compare word data to GPR and decrement GPR by 1/2 | 2 / 4 |
| CMPI1/2 | Compare word data to GPR and increment GPR by 1/2 | 2 / 4 |
| PRIOR | Determine number of shift cycles to normalize direct word GPR and store result in direct word GPR | 2 |
| SHL / SHR | Shift left/right direct word GPR | 2 |
| ROL / ROR | Rotate left/right direct word GPR | 2 |
| ASHR | Arithmetic (sign bit) shift right direct word GPR | 2 |
| MOV(B) | Move word (byte) data | 2 / 4 |
| MOVBS | Move byte operand to word operand with sign extension | 2 / 4 |
| MOVBZ | Move byte operand to word operand with zero extension | 2 / 4 |
| JMPA, JMPI, JMPR | Jump absolute/indirect/relative if condition is met | 4 |
| JMPS | Jump absolute to a code segment | 4 |

Table 27. Standard instruction set summary (continued)

| Mnemonic | Description | Bytes |
|---------------------|---|-------|
| J(N)B | Jump relative if direct bit is (not) set | 4 |
| JBC | Jump relative and clear bit if direct bit is set | 4 |
| JNBS | Jump relative and set bit if direct bit is not set | 4 |
| CALLA, CALLI, CALLR | Call absolute/indirect/relative subroutine if condition is met | 4 |
| CALLS | Call absolute subroutine in any code segment | 4 |
| PCALL | Push direct word register onto system stack and call absolute subroutine | 4 |
| TRAP | Call interrupt service routine via immediate trap number | 2 |
| PUSH, POP | Push/pop direct word register onto/from system stack | 2 |
| SCXT | Push direct word register onto system stack and update register with word operand | 4 |
| RET | Return from intra-segment subroutine | 2 |
| RETS | Return from inter-segment subroutine | 2 |
| RETP | Return from intra-segment subroutine and pop direct word register from system stack | 2 |
| RETI | Return from interrupt service subroutine | 2 |
| SRST | Software Reset | 4 |
| IDLE | Enter Idle Mode | 4 |
| PWRDN | Enter Power Down Mode (supposes $\overline{\text{NMI}}$ -pin being low) | 4 |
| SRVWDT | Service Watchdog Timer | 4 |
| DISWDT | Disable Watchdog Timer | 4 |
| EINIT | Signify End-of-Initialization on RSTOUT-pin | 4 |
| ATOMIC | Begin ATOMIC sequence | 2 |
| EXTR | Begin EXTended Register sequence | 2 |
| EXTP(R) | Begin EXTended Page (and Register) sequence | 2 / 4 |
| EXTS(R) | Begin EXTended Segment (and Register) sequence | 2 / 4 |
| NOP | Null operation | 2 |

7.3 MAC co-processor specific instructions

The [Table 28](#) lists the MAC instructions of the ST10F272. The detailed description of each instruction can be found in the “ST10 Family Programming Manual”. Note that all MAC instructions are encoded on 4 Bytes.

Table 28. MAC instruction set summary

| Mnemonic | Description |
|----------------------|--|
| CoABS | Absolute Value of the Accumulator |
| CoADD(2) | Addition |
| CoASHR(rnd) | Accumulator Arithmetic Shift Right & Optional Round |
| CoCMP | Compare Accumulator with Operands |
| CoLOAD(-,2) | Load Accumulator with Operands |
| CoMAC(R,u,s,-,rnd) | (Un)Signed/(Un)Signed Multiply-Accumulate & Optional Round |
| CoMACM(R)(u,s,-,rnd) | (Un)Signed/(Un)Signed Multiply-Accumulate with Parallel Data Move & Optional Round |
| CoMAX / CoMIN | Maximum / Minimum of Operands and Accumulator |
| CoMOV | Memory to Memory Move |
| CoMUL(u,s,-,rnd) | (Un)Signed/(Un)Signed multiply & Optional Round |
| CoNEG(rnd) | Negate Accumulator & Optional Round |
| CoNOP | No-Operation |
| CoRND | Round Accumulator |
| CoSHL / CoSHR | Accumulator Logical Shift Left / Right |
| CoSTORE | Store a MAC Unit Register |
| CoSUB(2,R) | Substraction |

8 External bus controller

All of the external memory accesses are performed by the on-chip external bus controller.

The EBC can be programmed to single chip mode when no external memory is required, or to one of four different external memory access modes:

- 16- / 18- / 20- / 24-bit addresses and 16-bit data, demultiplexed
- 16- / 18- / 20- / 24-bit addresses and 16-bit data, multiplexed
- 16- / 18- / 20- / 24-bit addresses and 8-bit data, multiplexed
- 16- / 18- / 20- / 24-bit addresses and 8-bit data, demultiplexed

In demultiplexed bus modes addresses are output on PORT1 and data is input / output on PORT0 or P0L, respectively. In the multiplexed bus modes both addresses and data use PORT0 for input / output.

Timing characteristics of the external bus interface (memory cycle time, memory tri-state time, length of ALE and read / write delay) are programmable giving the choice of a wide range of memories and external peripherals.

Up to four independent address windows may be defined (using register pairs ADDRSELx / BUSCONx) to access different resources and bus characteristics.

These address windows are arranged hierarchically where BUSCON4 overrides BUSCON3 and BUSCON2 overrides BUSCON1.

All accesses to locations not covered by these four address windows are controlled by BUSCON0. Up to five external $\overline{\text{CS}}$ signals (four windows plus default) can be generated in order to save external glue logic. Access to very slow memories is supported by a 'Ready' function.

A $\overline{\text{HOLD}}$ / $\overline{\text{HLDA}}$ protocol is available for bus arbitration which shares external resources with other bus masters.

The bus arbitration is enabled by setting bit HLDEN in register PSW. After setting HLDEN once, pins P6.7...P6.5 ($\overline{\text{BREQ}}$, $\overline{\text{HLDA}}$, $\overline{\text{HOLD}}$) are automatically controlled by the EBC. In master mode (default after reset) the $\overline{\text{HLDA}}$ pin is an output. By setting bit DP6.7 to '1' the slave mode is selected where pin $\overline{\text{HLDA}}$ is switched to input. This directly connects the slave controller to another master controller without glue logic.

For applications which require less external memory space, the address space can be restricted to 1 Mbyte, 256 Kbytes or to 64 Kbytes. Port 4 outputs all eight address lines if an address space of 16M Bytes is used, otherwise four, two or no address lines.

Chip select timing can be made programmable. By default (after reset), the $\overline{\text{CSx}}$ lines change half a CPU clock cycle after the rising edge of ALE. With the CSCFG bit set in the SYSCON register the $\overline{\text{CSx}}$ lines change with the rising edge of ALE.

The active level of the READY pin can be set by bit RDYPOL in the BUSCONx registers. When the READY function is enabled for a specific address window, each bus cycle within the window must be terminated with the active level defined by bit RDYPOL in the associated BUSCON register.

9 Interrupt system

The interrupt response time for internal program execution is from 78ns to 187.5ns at 64 MHz CPU clock.

The ST10F272 architecture supports several mechanisms for fast and flexible response to service requests that can be generated from various sources (internal or external) to the microcontroller. Any of these interrupt requests can be serviced by the Interrupt Controller or by the Peripheral Event Controller (PEC).

In contrast to a standard interrupt service where the current program execution is suspended and a branch to the interrupt vector table is performed, just one cycle is 'stolen' from the current CPU activity to perform a PEC service. A PEC service implies a single Byte or Word data transfer between any two memory locations with an additional increment of either the PEC source or destination pointer. An individual PEC transfer counter is implicitly decremented for each PEC service except when performing in the continuous transfer mode. When this counter reaches zero, a standard interrupt is performed to the corresponding source related vector location. PEC services are very well suited to perform the transmission or the reception of blocks of data. The ST10F272 has 8 PEC channels, each of them offers such fast interrupt-driven data transfer capabilities.

An interrupt control register which contains an interrupt request flag, an interrupt enable flag and an interrupt priority bit-field is dedicated to each existing interrupt source. Thanks to its related register, each source can be programmed to one of sixteen interrupt priority levels. Once starting to be processed by the CPU, an interrupt service can only be interrupted by a higher prioritized service request. For the standard interrupt processing, each of the possible interrupt sources has a dedicated vector location.

Software interrupts are supported by means of the 'TRAP' instruction in combination with an individual trap (interrupt) number.

Fast external interrupt inputs are provided to service external interrupts with high precision requirements. These fast interrupt inputs feature programmable edge detection (rising edge, falling edge or both edges).

Fast external interrupts may also have interrupt sources selected from other peripherals; for example the CANx controller receive signals (CANx_RxD) and I²C serial clock signal can be used to interrupt the system.

Table 29 shows all the available ST10F272 interrupt sources and the corresponding hardware-related interrupt flags, vectors, vector locations and trap (interrupt) numbers:

Table 29. Interrupt sources

| Source of Interrupt or PEC Service Request | Request Flag | Enable Flag | Interrupt Vector | Vector Location | Trap Number |
|--|--------------|-------------|------------------|-----------------|-------------|
| CAPCOM Register 0 | CC0IR | CC0IE | CC0INT | 00'0040h | 10h |
| CAPCOM Register 1 | CC1IR | CC1IE | CC1INT | 00'0044h | 11h |

Hardware traps are exceptions or error conditions that arise during run-time. They cause immediate non-maskable system reaction similar to a standard interrupt service (branching to a dedicated vector table location).

The occurrence of a hardware trap is additionally signified by an individual bit in the trap flag register (TFR). Except when another higher prioritized trap service is in progress, a hardware trap will interrupt any other program execution. Hardware trap services cannot not be interrupted by standard interrupt or by PEC interrupts.

9.1 X-Peripheral interrupt

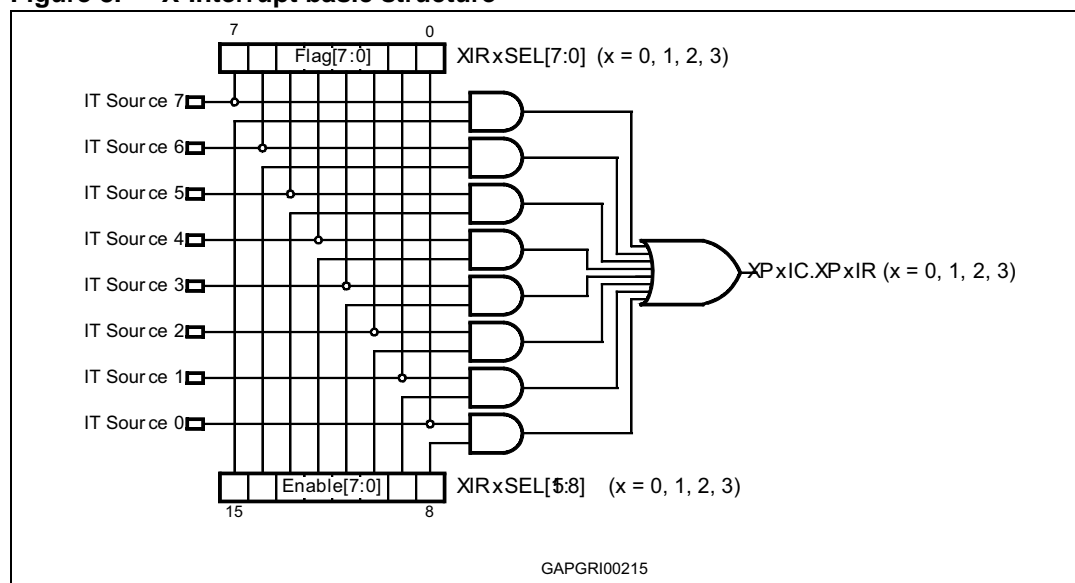

The limited number of X-Bus interrupt lines of the present ST10 architecture, imposes some constraints on the implementation of the new functionality. In particular, the additional X-Peripherals SSC1, ASC1, I²C, PWM1 and RTC need some resources to implement interrupt and PEC transfer capabilities. For this reason, a multiplexed structure for the interrupt management is proposed. In the next [Figure 8](#), the principle is explained through a simple diagram, which shows the basic structure replicated for each of the four X-interrupt available vectors (XP0INT, XP1INT, XP2INT and XP3INT).

It is based on a set of 16-bit registers XIRxSEL (x=0,1,2,3), divided in two portions each:

- Byte High XIRxSEL[15:8] Interrupt Enable bits
- Byte Low XIRxSEL[7:0] Interrupt Flag bits

When different sources submit an interrupt request, the enable bits (Byte High of XIRxSEL register) define a mask which controls which sources will be associated with the unique available vector. If more than one source is enabled to issue the request, the service routine will have to take care to identify the real event to be serviced. This can easily be done by checking the flag bits (Byte Low of XIRxSEL register). Note that the flag bits can also provide information about events which are not currently serviced by the interrupt controller (since masked through the enable bits), allowing an effective software management also in absence of the possibility to serve the related interrupt request: a periodic polling of the flag bits may be implemented inside the user application.

Figure 8. X-Interrupt basic structure

The [Table 30](#) summarizes the mapping of the different interrupt sources which shares the four X-interrupt vectors.

Table 30. X-Interrupt detailed mapping

| | XP0INT | XP1INT | XP2INT | XP3INT |
|-----------------------|--------|--------|--------|--------|
| CAN1 Interrupt | x | | | x |
| CAN2 Interrupt | | x | | x |
| I2C Receive | x | x | x | |
| I2C Transmit | x | x | x | |
| I2C Error | | | | x |
| SSC1 Receive | x | x | x | |
| SSC1 Transmit | x | x | x | |
| SSC1 Error | | | | x |
| ASC1 Receive | x | x | x | |

Table 30. X-Interrupt detailed mapping (continued)

| | XP0INT | XP1INT | XP2INT | XP3INT |
|----------------------|--------|--------|--------|--------|
| ASC1 Transmit | x | x | x | |
| ASC1 Transmit Buffer | x | x | x | |
| ASC1 Error | | | | x |
| PLL Unlock / OWD | | | | x |
| PWM1 Channel 3...0 | | | x | x |

9.2 Exception and error traps list

[Table 31](#) shows all of the possible exceptions or error conditions that can arise during run-time.

Table 31. Trap priorities

| Exception condition | Trap flag | Trap vector | Vector location | Trap number | Trap* priority |
|--|--|--|--|--|----------------------------|
| Reset Functions: Hardware Reset Software Reset Watchdog Timer Overflow | | RESET RESET RESET | 00'0000h 00'0000h 00'0000h | 00h 00h 00h | III III III |
| Class A Hardware Traps: Non-Maskable Interrupt Stack Overflow Stack Underflow | NMI STKOF STKUF | NMITRAP STOTRAP STUTRAP | 00'0008h 00'0010h 00'0018h | 02h 04h 06h | II II II |
| Class B Hardware Traps: Undefined Opcode MAC Interruption Protected Instruction Fault Illegal word Operand Access Illegal Instruction Access Illegal External Bus Access | UNDOPC MACTRP PRTFLT ILLOPA ILLINA ILLBUS | BTRAP BTRAP BTRAP BTRAP BTRAP BTRAP | 00'0028h 00'0028h 00'0028h 00'0028h 00'0028h 00'0028h | 0Ah 0Ah 0Ah 0Ah 0Ah 0Ah | I I I I I I |
| Reserved | | | [002Ch - 003Ch] | [0Bh - 0Fh] | |
| Software Traps TRAP Instruction | | | Any 0000h – 01FCh in steps of 4h | Any [00h - 7Fh] | Current CPU Priority |

Note: * - All the class B traps have the same trap number (and vector) and the same lower priority compare to the class A traps and to the resets.

- Each class A traps has a dedicated trap number (and vector). They are prioritized in the second priority level.

- The resets have the highest priority level and the same trap number.

- The PSW.ILVL CPU priority is forced to the highest level (15) when these exceptions are serviced.

10 Capture / compare (CAPCOM) units

The ST10F272 has two 16-channel CAPCOM units which support generation and control of timing sequences on up to 32 channels with a maximum resolution of 125ns at 64 MHz CPU clock.

The CAPCOM units are typically used to handle high speed I/O tasks such as pulse and waveform generation, pulse width modulation (PMW), Digital to Analog (D/A) conversion, software timing, or time recording relative to external events.

Four 16-bit timers (T0/T1, T7/T8) with reload registers provide two independent time bases for the capture/compare register array.

The input clock for the timers is programmable to several prescaled values of the internal system clock, or may be derived from an overflow/underflow of timer T6 in module GPT2.

This provides a wide range of variation for the timer period and resolution and allows precise adjustments to application specific requirements. In addition, external count inputs for CAPCOM timers T0 and T7 allow event scheduling for the capture/compare registers relative to external events.

Each of the two capture/compare register arrays contain 16 dual purpose capture/compare registers, each of which may be individually allocated to either CAPCOM timer T0 or T1 (T7 or T8, respectively), and programmed for capture or compare functions. Each of the 32 registers has one associated port pin which serves as an input pin for triggering the capture function, or as an output pin to indicate the occurrence of a compare event.

When a capture/compare register has been selected for capture mode, the current contents of the allocated timer will be latched (captured) into the capture/compare register in response to an external event at the port pin which is associated with this register. In addition, a specific interrupt request for this capture/compare register is generated.

Either a positive, a negative, or both a positive and a negative external signal transition at the pin can be selected as the triggering event. The contents of all registers which have been selected for one of the five compare modes are continuously compared with the contents of the allocated timers.

When a match occurs between the timer value and the value in a capture / compare register, specific actions will be taken based on the selected compare mode.

The input frequencies f_{Tx} , for the timer input selector Tx, are determined as a function of the CPU clocks. The timer input frequencies, resolution and periods which result from the selected pre-scaler option in Tx1 when using a 40 MHz and 64 MHz CPU clock are listed in the [Table 33](#) and [Table 34](#) respectively.

The numbers for the timer periods are based on a reload value of 0000h. Note that some numbers may be rounded to 3 significant figures.

Table 32. Compare modes

| Compare modes | Function |
|----------------------|--|
| Mode 0 | Interrupt-only compare mode; several compare interrupts per timer period are possible |
| Mode 1 | Pin toggles on each compare match; several compare events per timer period are possible |
| Mode 2 | Interrupt-only compare mode; only one compare interrupt per timer period is generated |
| Mode 3 | Pin set '1' on match; pin reset '0' on compare time overflow; only one compare event per timer period is generated |
| Double Register Mode | Two registers operate on one pin; pin toggles on each compare match; several compare events per timer period are possible. |

Table 33. CAPCOM timer input frequencies, resolutions and periods at 40 MHz

| f _{CPU} = 40 MHz | Timer input selection txl | | | | | | | |
|---------------------------------|---------------------------|--------|---------|----------|-----------|------------|------------|----------|
| | 000b | 001b | 010b | 011b | 100b | 101b | 110b | 111b |

| Resolution | 125ns | 250ns | 0.5µs | 1.0µs | 2.0µs | 4.0µs | 8.0µs | 16.0µs |
| Period | 8.2ms | 16.4ms | 32.8ms | 65.5ms | 131.1ms | 262.1ms | 524.3ms | 1.049s |

11 General purpose timer unit

The GPT unit is a flexible multifunctional timer/counter structure which is used for time related tasks such as event timing and counting, pulse width and duty cycle measurements, pulse generation, or pulse multiplication. The GPT unit contains five 16-bit timers organized into two separate modules GPT1 and GPT2. Each timer in each module may operate independently in several different modes, or may be concatenated with another timer of the same module.

11.1 GPT1

Each of the three timers T2, T3, T4 of the GPT1 module can be configured individually for one of four basic modes of operation: **timer**, **gated timer**, **counter mode** and **incremental interface mode**.

In timer mode, the input clock for a timer is derived from the CPU clock, divided by a programmable prescaler.

In counter mode, the timer is clocked in reference to external events.

Pulse width or duty cycle measurement is supported in gated timer mode where the operation of a timer is controlled by the 'gate' level on an external input pin. For these purposes, each timer has one associated port pin (TxIN) which serves as gate or clock input.

Table 35 and Table 36 list the timer input frequencies, resolution and periods for each pre-scaler option at 40MHz and 64MHz CPU clock respectively.

In Incremental Interface Mode, the GPT1 timers (T2, T3, T4) can be directly connected to the incremental position sensor signals A and B by their respective inputs TxIN and TxEUD.

Direction and count signals are internally derived from these two input signals so that the contents of the respective timer Tx corresponds to the sensor position. The third position sensor signal TOP0 can be connected to an interrupt input.

Timer T3 has output toggle latches (TxOTL) which changes state on each timer over flow / underflow. The state of this latch may be output on port pins (TxOUT) for time out monitoring of external hardware components, or may be used internally to clock timers T2 and T4 for high resolution of long duration measurements.

In addition to their basic operating modes, timers T2 and T4 may be configured as reload or capture registers for timer T3.

Figure 9. Block diagram of GPT1

11.2 GPT2

The GPT2 module provides precise event control and time measurement. It includes two timers (T5, T6) and a capture/reload register (CAPREL). Both timers can be clocked with an input clock which is derived from the CPU clock via a programmable prescaler or with external signals. The count direction (up/down) for each timer is programmable by software or may additionally be altered dynamically by an external signal on a port pin (TxEUD). Concatenation of the timers is supported via the output toggle latch (T6OTL) of timer T6 which changes its state on each timer overflow/underflow.

The state of this latch may be used to clock timer T5, or it may be output on a port pin (T6OUT). The overflow / underflow of timer T6 can additionally be used to clock the CAPCOM timers T0 or T1, and to cause a reload from the CAPREL register. The CAPREL register may capture the contents of timer T5 based on an external signal transition on the corresponding port pin (CAPIN), and timer T5 may optionally be cleared after the capture procedure. This allows absolute time differences to be measured or pulse multiplication to be performed without software overhead.

The capture trigger (timer T5 to CAPREL) may also be generated upon transitions of GPT1 timer T3 inputs T3IN and/or T3EUD. This is advantageous when T3 operates in Incremental Interface Mode.

[Table 37](#) and [Table 38](#) list the timer input frequencies, resolution and periods for each pre-scaler option at 40MHz and 64MHz CPU clock respectively.

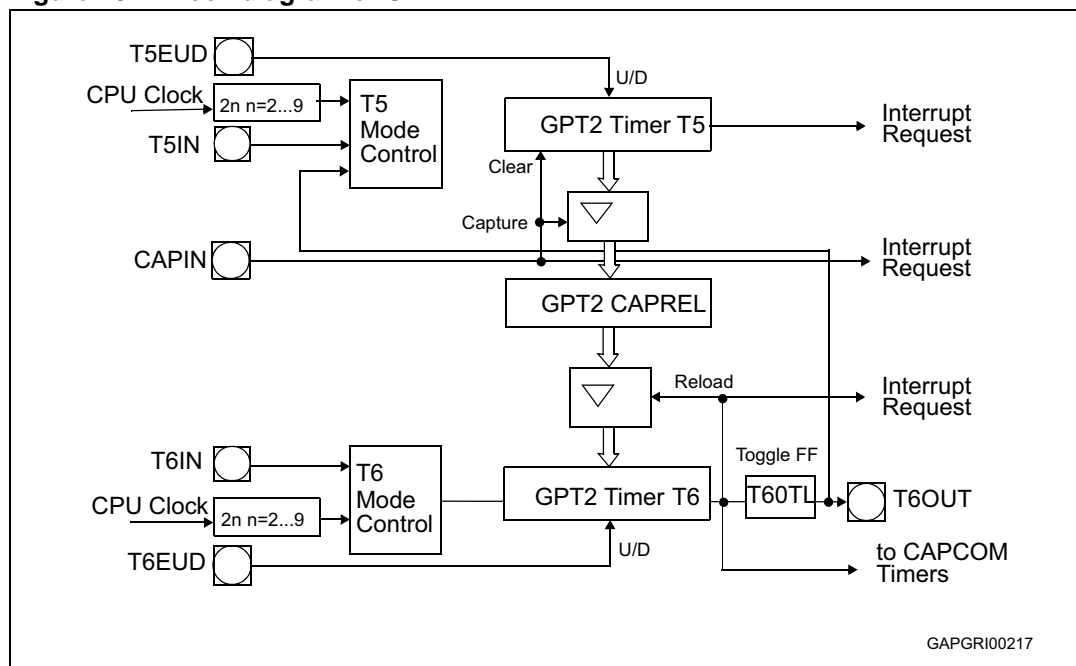

Table 37. GPT2 timer input frequencies, resolutions and periods at 40 MHz

| $f_{\text{CPU}} = 40\text{MHz}$ | Timer Input Selection T5I / T6I | | | | | | | |

12 PWM modules

Two pulse width modulation modules are available on ST10F272: standard PWM0 and XBUS PWM1. They can generate up to four PWM output signals each, using edge-aligned or centre-aligned PWM. In addition, the PWM modules can generate PWM burst signals and single shot outputs. The [Table 39](#) and [Table 40](#) show the PWM frequencies for different resolutions. The level of the output signals is selectable and the PWM modules can generate interrupt requests.

Figure 11. Block diagram of PWM module

Table 39. PWM unit frequencies and resolutions at 40 MHz CPU clock

| Mode 0 | Resolution | 8-bit | 10-bit | 12-bit | 14-bit | 16-bit |
|--------------|------------|------------|-----------|----------|----------|---------|
| CPU Clock/1 | 25ns | 156.25 kHz | 39.1 kHz | 9.77 kHz | 2.44Hz | 610Hz |
| CPU Clock/64 | 1.6µs | 2.44 kHz | 610Hz | 152.6Hz | 38.15Hz | 9.54Hz |
| Mode 1 | Resolution | 8-bit | 10-bit | 12-bit | 14-bit | 16-bit |
| CPU Clock/1 | 25ns | 78.12 kHz | 19.53 kHz | 4.88 kHz | 1.22 kHz | 305.2Hz |
| CPU Clock/64 | 1.6µs | 1.22 kHz | 305.17Hz | 76.29Hz | 19.07Hz | 4.77Hz |

Table 40. PWM unit frequencies and resolutions at 64 MHz CPU clock

| Mode 0 | Resolution | 8-bit | 10-bit | 12-bit | 14-bit | 16-bit |
|---------------|-------------------|--------------|---------------|---------------|---------------|---------------|
| CPU Clock/1 | 15.6ns | 250 kHz | 62.5 kHz | 15.63 kHz | 3.91Hz | 977Hz |

13 Parallel ports

13.1 Introduction

The ST10F272 MCU provides up to 111 I/O lines with programmable features. These capabilities bring very flexible adaptation of this MCU to wide range of applications.

ST10F272 has nine groups of I/O lines gathered as follows:

- Port 0 is a two time 8-bit port named P0L (Low as less significant byte) and P0H (high as most significant byte)
- Port 1 is a two time 8-bit port named P1L and P1H
- Port 2 is a 16-bit port
- Port 3 is a 15-bit port (P3.14 line is not implemented)
- Port 4 is a 8-bit port
- Port 5 is a 16-bit port input only
- Port 6, Port 7 and Port 8 are 8-bit ports

These ports may be used as general purpose bidirectional input or output, software controlled with dedicated registers.

For example, the output drivers of six of the ports (2, 3, 4, 6, 7, 8) can be configured (bit-wise) for push-pull or open drain operation using ODPx registers.

The input threshold levels are programmable (TTL/CMOS) for all the ports. The logic level of a pin is clocked into the input latch once per state time, regardless whether the port is configured for input or output. The threshold is selected with PICON and XPICON registers control bits.

A write operation to a port pin configured as an input causes the value to be written into the port output latch, while a read operation returns the latched state of the pin itself. A read-modify-write operation reads the value of the pin, modifies it, and writes it back to the output latch.

Writing to a pin configured as an output (DPx.y='1') causes the output latch and the pin to have the written value, since the output buffer is enabled. Reading this pin returns the value of the output latch. A read-modify-write operation reads the value of the output latch, modifies it, and writes it back to the output latch, thus also modifying the level at the pin.

I/O lines support an alternate function which is detailed in the following description of each port.

13.2 I/O's special features

13.2.1 Open drain mode

Some of the I/O ports of ST10F272 support the open drain capability. This programmable feature may be used with an external pull-up resistor, in order to get an AND wired logical function.

This feature is implemented for ports P2, P3, P4, P6, P7 and P8 (see respective sections), and is controlled through the respective Open Drain Control Registers ODPx.

13.2.2 Input threshold control

The standard inputs of the ST10F272 determine the status of input signals according to TTL levels. In order to accept and recognize noisy signals, CMOS input thresholds can be selected instead of the standard TTL thresholds for all the pins. These CMOS thresholds are defined above the TTL thresholds and feature a higher hysteresis to prevent the inputs from toggling while the respective input signal level is near the thresholds.

The Port Input Control registers PICON and XPICON are used to select these thresholds for each Byte of the indicated ports, this means the 8-bit ports P0L, P0H, P1L, P1H, P4, P7 and P8 are controlled by one bit each while ports P2, P3 and P5 are controlled by two bits each.

All options for individual direction and output mode control are available for each pin, independent of the selected input threshold.

13.3 Alternate port functions

Each port line has one associated programmable alternate input or output function.

- PORT0 and PORT1 may be used as address and data lines when accessing external memory. Besides, PORT1 provides also:
 - Input capture lines
 - 8 additional analog input channels to the A/D converter
- Port 2, Port 7 and Port 8 are associated with the capture inputs or compare outputs of the CAPCOM units and/or with the outputs of the PWM0 module, of the PWM1 module and of the ASC1.
Port 2 is also used for fast external interrupt inputs and for timer 7 input.
- Port 3 includes the alternate functions of timers, serial interfaces, the optional bus control signal BHE and the system clock output (CLKOUT).
- Port 4 outputs the additional segment address bit A23...A16 in systems where more than 64 Kbytes of memory are to be access directly. In addition, CAN1, CAN2 and I²C lines are provided.
- Port 5 is used as analog input channels of the A/D converter or as timer control signals.
- Port 6 provides optional bus arbitration signals ($\overline{\text{BREQ}}$, $\overline{\text{HLDA}}$, $\overline{\text{HOLD}}$) and chip select signals and the SSC1 lines.

If the alternate output function of a pin is to be used, the direction of this pin must be programmed for output (DPx.y='1'), except for some signals that are used directly after reset and are configured automatically. Otherwise the pin remains in the high-impedance state and is not effected by the alternate output function. The respective port latch should hold a '1', because its output is ANDed with the alternate output data (except for PWM output signals).

If the alternate input function of a pin is used, the direction of the pin must be programmed for input (DPx.y='0') if an external device is driving the pin. The input direction is the default after reset. If no external device is connected to the pin, however, one can also set the direction for this pin to output. In this case, the pin reflects the state of the port output latch. Thus, the alternate input function reads the value stored in the port output latch. This can be used for testing purposes to allow a software trigger of an alternate input function by writing to the port output latch.

On most of the port lines, the user software is responsible for setting the proper direction when using an alternate input or output function of a pin.

This is done by setting or clearing the direction control bit DPx.y of the pin before enabling the alternate function.

There are port lines, however, where the direction of the port line is switched automatically.

For instance, in the multiplexed external bus modes of PORT0, the direction must be switched several times for an instruction fetch in order to output the addresses and to input the data.

Obviously, this cannot be done through instructions. In these cases, the direction of the port line is switched automatically by hardware if the alternate function of such a pin is enabled.

To determine the appropriate level of the port output latches check how the alternate data output is combined with the respective port latch output.

There is one basic structure for all port lines with only an alternate input function. Port lines with only an alternate output function, however, have different structures due to the way the direction of the pin is switched and depending on whether the pin is accessible by the user software or not in the alternate function mode.

All port lines that are not used for these alternate functions may be used as general purpose I/O lines.

14 A/D converter

A 10-bit A/D converter with 16+8 multiplexed input channels and a sample and hold circuit is integrated on-chip. An automatic self-calibration adjusts the A/D converter module to process parameter variations at each reset event. The sample time (for loading the capacitors) and the conversion time is programmable and can be adjusted to the external circuitry.

The ST10F272E has 16+8 multiplexed input channels on Port 5 and Port 1. The selection between Port 5 and Port 1 is made via a bit in a XBus register. Refer to the User Manual for a detailed description.

A different accuracy is guaranteed (Total Unadjusted Error) on Port 5 and Port 1 analog channels (with higher restrictions when overload conditions occur); in particular, Port 5 channels are more accurate than the Port 1 ones. Refer to [Section 24: Electrical characteristics](#).

The A/D converter input bandwidth is limited by the achievable accuracy: supposing a maximum error of 0.5LSB (2mV) impacting the global TUE (TUE depends also on other causes), in worst case of temperature and process, the maximum frequency for a sine wave analog signal is around 7.5 kHz. Of course, to reduce the effect of the input signal variation on the accuracy down to 0.05LSB, the maximum input frequency of the sine wave shall be reduced to 800 Hz.

If static signal is applied during sampling phase, series resistance shall not be greater than 20k Ω (this taking into account eventual input leakage). It is suggested to not connect any capacitance on analog input pins, in order to reduce the effect of charge partitioning (and consequent voltage drop error) between the external and the internal capacitance: in case an RC filter is necessary the external capacitance must be greater than 10nF to minimize the accuracy impact.

Overrun error detection / protection is controlled by the ADDAT register. Either an interrupt request is generated when the result of a previous conversion has not been read from the result register at the time the next conversion is complete, or the next conversion is suspended until the previous result has been read. For applications which require less than 16+8 analog input channels, the remaining channel inputs can be used as digital input port pins.

The A/D converter of the ST10F272 supports different conversion modes:

- **Single channel single conversion:** The analog level of the selected channel is sampled once and converted. The result of the conversion is stored in the ADDAT register.
- **Single channel continuous conversion:** The analog level of the selected channel is repeatedly sampled and converted. The result of the conversion is stored in the ADDAT register.
- **Auto scan single conversion:** The analog level of the selected channels are sampled once and converted. After each conversion the result is stored in the ADDAT register. The data can be transferred to the RAM by interrupt software management or using the powerful Peripheral Event Controller (PEC) data transfer.
- **Auto scan continuous conversion:** The analog level of the selected channels are repeatedly sampled and converted. The result of the conversion is stored in the ADDAT

register. The data can be transferred to the RAM by interrupt software management or using the PEC data transfer.

- **Wait for ADDAT read mode:** When using continuous modes, in order to avoid to overwrite the result of the current conversion by the next one, the ADWR bit of ADCON control register must be activated. Then, until the ADDAT register is read, the new result is stored in a temporary buffer and the conversion is on hold.
- **Channel injection mode:** When using continuous modes, a selected channel can be converted in between without changing the current operating mode. The 10-bit data of the conversion are stored in ADRES field of ADDAT2. The current continuous mode remains active after the single conversion is completed.

A full calibration sequence is performed after a reset. This full calibration lasts up to 40.630 CPU clock cycles. During this time, the busy flag ADBSY is set to indicate the operation. It compensates the capacitance mismatch, so the calibration procedure does not need any update during normal operation.

No conversion can be performed during this time: the bit ADBSY shall be polled to verify when the calibration is over, and the module is able to start a conversion.

15 Serial channels

Serial communication with other microcontrollers, microprocessors, terminals or external peripheral components is provided by up to four serial interfaces: two asynchronous / synchronous serial channels (ASC0 and ASC1) and two high-speed synchronous serial channel (SSC0 and SSC1). Dedicated Baud rate generators set up all standard Baud rates without the requirement of oscillator tuning. For transmission, reception and erroneous reception, separate interrupt vectors are provided for ASC0 and SSC0 serial channel. A more complex mechanism of interrupt sources multiplexing is implemented for ASC1 and SSC1 (XBUS mapped).

15.1 Asynchronous / synchronous serial interfaces

The asynchronous / synchronous serial interfaces (ASC0 and ASC1) provides serial communication between the ST10F272 and other microcontrollers, microprocessors or external peripherals.

15.2 ASCx in asynchronous mode

In asynchronous mode, 8- or 9-bit data transfer, parity generation and the number of stop bits can be selected. Parity framing and overrun error detection is provided to increase the reliability of data transfers. Transmission and reception of data is double-buffered. Full-duplex communication up to 2M Bauds (at 64 MHz of f_{CPU}) is supported in this mode.

Table 41. ASC asynchronous baud rates by reload value and deviation errors ($f_{CPU} = 40$ MHz)

| S0BRS = '0', $f_{CPU} = 40$ MHz | | | S0BRS = '1', $f_{CPU} = 40$ MHz | | |
|---------------------------------|-----------------|--------------------|---------------------------------|-----------------|--------------------|
| Baud rate (Baud) | Deviation error | Reload value (hex) | Baud rate (Baud) | Deviation error | Reload value (hex) |
| 1 250 000 | 0.0% / 0.0% | 0000 / 0000 | 833 333 | 0.0% / 0.0% | 0000 / 0000 |

| 153 | 0.0% / 0.0% | 1FE8 / 1FE9 | 102 | 0.0% / 0.0% | 1FE8 / 1FE9 |

Table 42. ASC asynchronous baud rates by reload value and deviation errors ($f_{CPU} = 64$ MHz)

| S0BRS = '0', $f_{CPU} = 64$ MHz | | | S0BRS = '1', $f_{CPU} = 64$ MHz | | |
|---------------------------------|-----------------|--------------------|---------------------------------|-----------------|--------------------|
| Baud rate (baud) | Deviation error | Reload value (hex) | Baud rate (baud) | Deviation error | Reload value (hex) |
| 2 000 000 | 0.0% / 0.0% | 0000 / 0000 | 1 333 333 | 0.0% / 0.0% | 0000 / 0000 |
| 112 000 | +1.5% / -7.0% | 0010 / 0011 | 112 000 | +6.3% / -7.0% | 000A / 000B |
| 56 000 | +1.5% / -3.0% | 0022 / 0023 | 56 000 | +6.3% / -0.8% | 0016 / 0017 |
| 38 400 | +1.7% / -1.4% | 0033 / 0034 | 38 400 | +3.3% / -1.4% | 0021 / 0022 |
| 19 200 | +0.2% / -1.4% | 0067 / 0068 | 19 200 | +0.9% / -1.4% | 0044 / 0045 |
| 9 600 | +0.2% / -0.6% | 00CF / 00D0 | 9 600 | +0.9% / -0.2% | 0089 / 008A |
| 4 800 | +0.2% / -0.2% | 019F / 01A0 | 4 800 | +0.4% / -0.2% | 0114 / 0115 |
| 2 400 | +0.2% / 0.0% | 0340 / 0341 | 2 400 | +0.1% / -0.2% | 022A / 015B |
| 1 200 | 0.1% / 0.0% | 0681 / 0682 | 1 200 | +0.1% / -0.1% | 0456 / 0457 |
| 600 | 0.0% / 0.0% | 0D04 / 0D05 | 600 | +0.1% / 0.0% | 08AD / 08AE |
| 300 | 0.0% / 0.0% | 1A09 / 1A0A | 300 | 0.0% / 0.0% | 115B / 115C |
| 245 | 0.0% / 0.0% | 1FE2 / 1FE3 | 163 | 0.0% / 0.0% | 1FF2 / 1FF3 |

Note: The deviation errors given in the [Table 41](#) and [Table 42](#) are rounded. To avoid deviation errors use a Baud rate crystal (providing a multiple of the ASC0 sampling frequency).

15.3 ASCx in synchronous mode

In synchronous mode, data is transmitted or received synchronously to a shift clock which is generated by the ST10F272. Half-duplex communication up to 8M Baud (at 40 MHz of f_{CPU}) is possible in this mode.

Table 43. ASC synchronous baud rates by reload value and deviation errors ($f_{CPU} = 40$ MHz)

| S0BRS = '0', $f_{CPU} = 40$ MHz | | | S0BRS = '1', $f_{CPU} = 40$ MHz | | |
|---------------------------------|-----------------|--------------------|---------------------------------|-----------------|--------------------|
| Baud rate (baud) | Deviation error | Reload value (hex) | Baud rate (baud) | Deviation error | Reload value (hex) |
| 5 000 000 | 0.0% / 0.0% | 0000 / 0000 | 3 333 333 | 0.0% / 0.0% | 0000 / 0000 |

| | | | 652 | 0.0% / 0.0% | 1FF2 / 1FF3 |

Note: The deviation errors given in the [Table 43](#) and [Table 44](#) are rounded. To avoid deviation errors use a Baud rate crystal (providing a multiple of the ASC0 sampling frequency)

15.4 High speed synchronous serial interfaces

The High-Speed Synchronous Serial Interfaces (SSC0 and SSC1) provides flexible high-speed serial communication between the ST10F272 and other microcontrollers, microprocessors or external peripherals.

The SSCx supports full-duplex and half-duplex synchronous communication. The serial clock signal can be generated by the SSCx itself (master mode) or be received from an external master (slave mode). Data width, shift direction, clock polarity and phase are programmable.

This allows communication with SPI-compatible devices. Transmission and reception of data is double-buffered. A 16-bit Baud rate generator provides the SSCx with a separate serial clock signal. The serial channel SSCx has its own dedicated 16-bit Baud rate generator with 16-bit reload capability, allowing Baud rate generation independent from the timers.

[Table 45](#) and [Table 46](#) list some possible Baud rates against the required reload values and the resulting bit times for 40 MHz and 64 MHz CPU clock respectively. The maximum is anyway limited to 8Mbaud.

Table 45. Synchronous baud rate and reload values ($f_{\text{CPU}} = 40 \text{ MHz}$)

| Baud rate | Bit time | Reload value |
|--|-------------|--------------|
| Reserved | --- | 0000h |
| Can be used only with $f_{\text{CPU}} = 32 \text{ MHz}$ (or lower) | --- | 0001h |
| 6.6M Baud | 150ns | 0002h |
| 5M Baud | 200ns | 0003h |
| 2.5M Baud | 400ns | 0007h |
| 1M Baud | 1 μ s | 0013h |
| 100K Baud | 10 μ s | 00C7h |
| 10K Baud | 100 μ s | 07CFh |
| 1K Baud | 1ms | 4E1Fh |
| 306 Baud | 3.26ms | FF4Eh |

Table 46. Synchronous baud rate and reload values ($f_{\text{CPU}} = 64 \text{ MHz}$)

| Baud rate | Bit time | Reload value |
|--|-------------|--------------|
| Reserved | --- | 0000h |
| Can be used only with $f_{\text{CPU}} = 32 \text{ MHz}$ (or lower) | --- | 0001h |
| Can be used only with $f_{\text{CPU}} = 48 \text{ MHz}$ (or lower) | --- | 0002h |
| 8M Baud | 125ns | 0003h |

16 I2C interface

The integrated I²C Bus Module handles the transmission and reception of frames over the two-line SDA/SCL in accordance with the I²C Bus specification. The I²C Module can operate in slave mode, in master mode or in multi-master mode. It can receive and transmit data using 7-bit or 10-bit addressing. Data can be transferred at speeds up to 400 Kbit/s (both Standard and Fast I²C bus modes are supported).

The module can generate three different types of interrupt:

- Requests related to bus events, like start or stop events, arbitration lost, etc.
- Requests related to data transmission
- Requests related to data reception

These requests are issued to the interrupt controller by three different lines, and identified as Error, Transmit, and Receive interrupt lines.

When the I²C module is enabled by setting bit XI2CEN in XPERCON register, pins P4.4 and P4.7 (where SCL and SDA are respectively mapped as alternate functions) are automatically configured as bidirectional open-drain: the value of the external pull-up resistor depends on the application. P4, DP4 and ODP4 cannot influence the pin configuration.

When the I²C cell is disabled (clearing bit XI2CEN), P4.4 and P4.7 pins are standard I/O controlled by P4, DP4 and ODP4.

The speed of the I²C interface may be selected between Standard mode (0 to 100 kHz) and Fast I²C mode (100 to 400 kHz).

17 CAN modules

The two integrated CAN modules (CAN1 and CAN2) are identical and handle the completely autonomous transmission and reception of CAN frames according to the CAN specification V2.0 part B (active). It is based on the C-CAN specification.

Each on-chip CAN module can receive and transmit standard frames with 11-bit identifiers as well as extended frames with 29-bit identifiers.

Because of duplication of the CAN controllers, the following adjustments are to be considered:

- Same internal register addresses of both CAN controllers, but with base addresses differing in address bit A8; separate chip select for each CAN module. Refer to [Section 4: Memory organization](#).
- The CAN1 transmit line (CAN1_TxD) is the alternate function of the Port P4.6 pin and the receive line (CAN1_RxD) is the alternate function of the Port P4.5 pin.
- The CAN2 transmit line (CAN2_TxD) is the alternate function of the Port P4.7 pin and the receive line (CAN2_RxD) is the alternate function of the Port P4.4 pin.
- Interrupt request lines of the CAN1 and CAN2 modules are connected to the XBUS interrupt lines together with other X-Peripherals sharing the four vectors.
- The CAN modules must be selected with corresponding CANxEN bit of XPERCON register before the bit XPEN of SYSCON register is set.
- The reset default configuration is: CAN1 enabled, CAN2 disabled.

Note: If one or both CAN modules is used, Port 4 cannot be programmed to output all 8 segment address lines. Thus, only four segment address lines can be used, reducing the external memory space to 5 Mbytes (1 Mbyte per CS line).

17.1 Configuration support

It is possible that both CAN controllers are working on the same CAN bus, supporting together up to 64 message objects. In this configuration, both receive signals and both transmit signals are linked together when using the same CAN transceiver. This configuration is especially supported by providing open drain outputs for the CAN1_TxD and CAN2_TxD signals. The open drain function is controlled with the ODP4 register for port P4: in this way it is possible to connect together P4.4 with P4.5 (receive lines) and P4.6 with P4.7 (transmit lines configured to be configured as Open-Drain).

The user is also allowed to map internally both CAN modules on the same pins P4.5 and P4.6. In this way, P4.4 and P4.7 may be used either as general purpose I/O lines, or used for I²C interface. This is possible by setting bit CANPAR of XMISC register. To access this register it is necessary to set bit XMISCEN of XPERCON register and bit XPEN of SYSCON register.

17.2 CAN bus configurations

Depending on application, CAN bus configuration may be one single bus with a single or multiple interfaces or a multiple bus with a single or multiple interfaces. The ST10F272 is able to support these two cases.

Single CAN bus

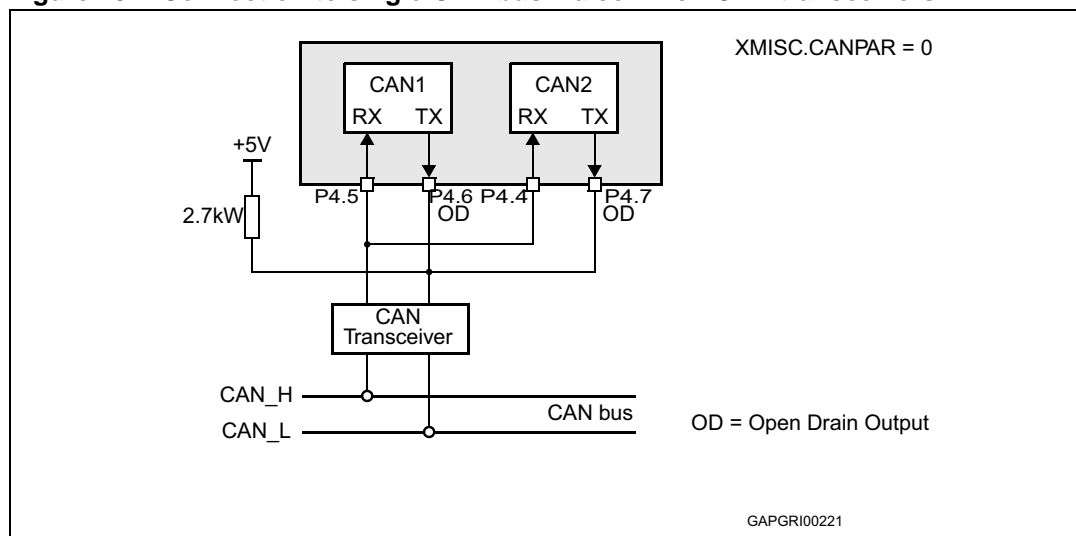

The single CAN Bus multiple interfaces configuration may be implemented using two CAN transceivers as shown in [Figure 12](#).

Figure 12. Connection to single CAN bus via separate CAN transceivers

The ST10F272 also supports single CAN Bus multiple (dual) interfaces using the open drain option of the CANx_TxD output as shown in [Figure 13](#). Thanks to the OR-Wired Connection, only one transceiver is required. In this case the design of the application must take in account the wire length and the noise environment.

Figure 13. Connection to single CAN bus via common CAN transceivers

Multiple CAN bus

The ST10F272 provides two CAN interfaces to support such kind of bus configuration as shown in [Figure 14](#).

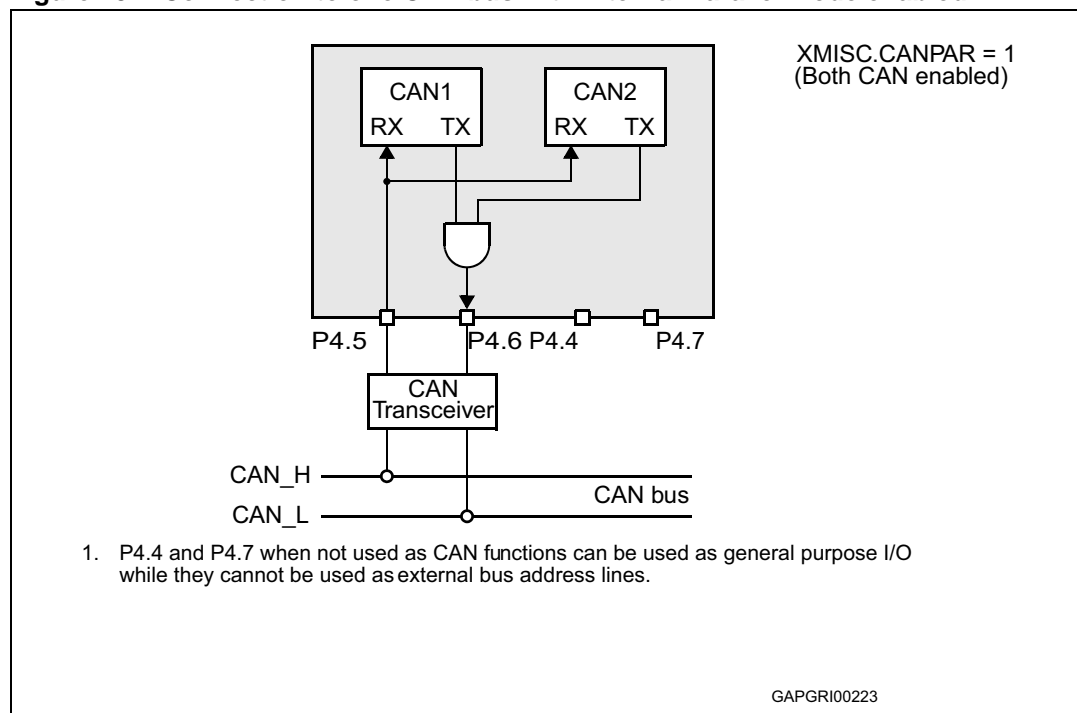

Figure 14. Connection to two different CAN buses (e.g. for gateway application)

Parallel Mode

In addition to previous configurations, a parallel mode is supported. This is shown in [Figure 15](#).

Figure 15. Connection to one CAN bus with internal Parallel Mode enabled

18 Real time clock

The Real Time Clock is an independent timer, in which the clock is derived directly from the clock oscillator on XTAL1 (main oscillator) input or XTAL3 input (32 kHz low-power oscillator) so that it can be kept on running even in Idle or Power down mode (if enabled to). Registers access is implemented onto the XBUS. This module is designed with the following characteristics:

- Generation of the current time and date for the system
- Cyclic time based interrupt, on Port2 external interrupts every 'RTC basic clock tick' and after n 'RTC basic clock ticks' (n is programmable) if enabled
- 58-bit timer for long term measurement
- Capability to exit the ST10 chip from Power down mode (if PWDCFG of SYSCON set) after a programmed delay

The real time clock is based on two main blocks of counters. The first block is a prescaler which generates a basic reference clock (for example a 1 second period). This basic reference clock is coming out of a 20-bit DIVIDER. This 20-bit counter is driven by an input clock derived from the on-chip CPU clock, pre-divided by a 1/64 fixed counter. This 20-bit counter is loaded at each basic reference clock period with the value of the 20-bit PRESCALER register. The value of the 20-bit RTCP register determines the period of the basic reference clock.

A timed interrupt request (RTCSI) may be sent on each basic reference clock period. The second block of the RTC is a 32-bit counter that may be initialized with the current system time. This counter is driven with the basic reference clock signal. In order to provide an alarm function the contents of the counter is compared with a 32-bit alarm register. The alarm register may be loaded with a reference date. An alarm interrupt request (RTCAI), may be generated when the value of the counter matches the alarm register.

The timed RTCSI and the alarm RTCAI interrupt requests can trigger a fast external interrupt via EXISEL register of port 2 and wake-up the ST10 chip when running power down mode. Using the RTCOFF bit of RTCCON register, the user may switch off the clock oscillator when entering the power down mode.

The last function implemented in the RTC is to switch off the main on-chip oscillator and the 32 kHz on chip oscillator if the ST10 enters the Power Down mode, so that the chip can be fully switched off (if RTC is disabled).

At power on, and after Reset phase, if the presence of a 32 kHz oscillation on XTAL3 / XTAL4 pins is detected, then the RTC counter is driven by this low frequency reference clock: when Power Down mode is entered, the RTC can either be stopped or left running, and in both the cases the main oscillator is turned off, reducing the power consumption of the device to the minimum required to keep on running the RTC counter and relative reference oscillator. This is valid also if Stand-by mode is entered (switching off the main supply V_{DD}), since both the RTC and the low power oscillator (32 kHz) are biased by the V_{STBY} . Vice versa, when at power on and after Reset, the 32 kHz is not present, the main oscillator drives the RTC counter, and since it is powered by the main power supply, it cannot be maintained running in Stand-by mode, while in Power Down mode the main oscillator is maintained running to provide the reference to the RTC module (if not disabled).

19 Watchdog timer

The Watchdog Timer is a fail-safe mechanism which prevents the microcontroller from malfunctioning for long periods of time.

The Watchdog Timer is always enabled after a reset of the chip and can only be disabled in the time interval until the EINIT (end of initialization) instruction has been executed.

Therefore, the chip start-up procedure is always monitored. The software must be designed to service the watchdog timer before it overflows. If, due to hardware or software related failures, the software fails to do so, the watchdog timer overflows and generates an internal hardware reset. It pulls the $\overline{\text{RSTOUT}}$ pin low in order to allow external hardware components to be reset.

Each of the different reset sources is indicated in the WDTCON register:

- Watchdog Timer Reset in case of an overflow
- Software Reset in case of execution of the SRST instruction
- Short, Long and Power-On Reset in case of hardware reset (and depending of reset pulse duration and RPD pin configuration)

The indicated bits are cleared with the EINIT instruction. The source of the reset can be identified during the initialization phase.

The Watchdog Timer is 16-bit, clocked with the system clock divided by 2 or 128. The high Byte of the watchdog timer register can be set to a pre-specified reload value (stored in WDTREL).

Each time it is serviced by the application software, the high byte of the watchdog timer is reloaded. For security, rewrite WDTCON each time before the watchdog timer is serviced

The [Table 47](#) and [Table 48](#) show the watchdog time range for 40 MHz and 64 MHz CPU clock respectively.

Table 47. WDTREL reload value ($f_{\text{CPU}} = 40 \text{ MHz}$)

| Reload value in WDTREL | Prescaler for $f_{\text{CPU}} = 40 \text{ MHz}$ | |
|------------------------|---|---------------------|
| | 2 (WDTIN = '0') | 128 (WDTIN = '1') |
| FFh | 12.8 μs | 819.2 μs |
| 00h | 3.277ms | 209.7ms |

Table 48. WDTREL reload value ($f_{\text{CPU}} = 64 \text{ MHz}$)

| Reload value in WDTREL | Prescaler for $f_{\text{CPU}} = 64 \text{ MHz}$ | |
|------------------------|---|-------------------|
| | 2 (WDTIN = '0') | 128 (WDTIN = '1') |
| FFh | 8 μs | 512 μs |
| 00h | 2.048ms | 131.1ms |

20 System reset

System reset initializes the MCU in a predefined state. There are six ways to activate a reset state. The system start-up configuration is different for each case as shown in [Table 49](#).

Table 49. Reset event definition

| Reset source | Flag | RPD status | Conditions |
|----------------------------------|------|---------------|---|
| Power-on reset | PONR | Low | Power-on |
| Asynchronous Hardware reset | LHWR | Low | $t_{\overline{RSTIN}} > ^1)$ |
| Synchronous Long Hardware reset | | High | $t_{\overline{RSTIN}} > (1032 + 12) \text{ TCL} + \max(4 \text{ TCL}, 500\text{ns})$ |
| Synchronous Short Hardware reset | SHWR | High | $t_{\overline{RSTIN}} > \max(4 \text{ TCL}, 500\text{ns})$ $t_{\overline{RSTIN}} \leq (1032 + 12) \text{ TCL} + \max(4 \text{ TCL}, 500\text{ns})$ |
| Watchdog Timer reset | WDTR | ³⁾ | WDT overflow |
| Software reset | SWR | ³⁾ | SRST instruction execution |

¹⁾ \overline{RSTIN} pulse should be longer than 500ns (Filter) and than settling time for configuration of Port0.

²⁾ See next [Section 20.1](#) for more details on minimum reset pulse duration.

³⁾ The RPD status has no influence unless Bidirectional Reset is activated (bit `BDRSTEN` in `SYSCON`): RPD low inhibits the Bidirectional reset on SW and WDT reset events, that is \overline{RSTIN} is not activated (refer to [Section 20.4](#), [Section 20.5](#) and [Section 20.6](#)).

20.1 Input filter

On \overline{RSTIN} input pin an on-chip RC filter is implemented. It is sized to filter all the spikes shorter than 50ns. On the other side, a valid pulse shall be longer than 500ns to grant that ST10 recognizes a reset command. In between 50ns and 500ns a pulse can either be filtered or recognized as valid, depending on the operating conditions and process variations.

For this reason all minimum durations mentioned in this Chapter for the different kind of reset events shall be carefully evaluated taking into account of the above requirements.

In particular, for Short Hardware Reset, where only 4 TCL is specified as minimum input reset pulse duration, the operating frequency is a key factor. Examples:

- For a CPU clock of 64 MHz, 4 TCL is 31.25ns, so it would be filtered. In this case the minimum becomes the one imposed by the filter (that is 500ns).
- For a CPU clock of 4 MHz, 4 TCL is 500ns. In this case the minimum from the formula is coherent with the limit imposed by the filter.

20.2 Asynchronous reset

An asynchronous reset is triggered when $\overline{\text{RSTIN}}$ pin is pulled low while RPD pin is at low level. Then the ST10F272 is immediately (after the input filter delay) forced in reset default state. It pulls low RSTOUT pin, it cancels pending internal hold states if any, it aborts all internal/external bus cycles, it switches buses (data, address and control signals) and I/O pin drivers to high-impedance, it pulls high Port0 pins.

Note: If an asynchronous reset occurs during a read or write phase in internal memories, the content of the memory itself could be corrupted: to avoid this, synchronous reset usage is strongly recommended.

Power-on reset

The asynchronous reset must be used during the power-on of the device. Depending on crystal or resonator frequency, the on-chip oscillator needs about 1ms to 10ms to stabilize (Refer to Electrical Characteristics Section), with an already stable V_{DD} . The logic of the ST10F272 does not need a stabilized clock signal to detect an asynchronous reset, so it is suitable for power-on conditions. To ensure a proper reset sequence, the $\overline{\text{RSTIN}}$ pin and the RPD pin must be held at low level until the device clock signal is stabilized and the system configuration value on Port0 is settled.

At Power-on it is important to respect some additional constraints introduced by the start-up phase of the different embedded modules.

In particular the on-chip voltage regulator needs at least 1ms to stabilize the internal 1.8V for the core logic: this time is computed from when the external reference (V_{DD}) becomes stable (inside specification range, that is at least 4.5V). This is a constraint for the application hardware (external voltage regulator): the $\overline{\text{RSTIN}}$ pin assertion shall be extended to guarantee the voltage regulator stabilization.

A second constraint is imposed by the embedded FLASH. When booting from internal memory, starting from $\overline{\text{RSTIN}}$ releasing, it needs a maximum of 1ms for its initialization: before that, the internal reset (RST signal) is not released, so the CPU does not start code execution in internal memory.

Note: This is not true if external memory is used (pin $\overline{\text{EA}}$ held low during reset phase). In this case, once $\overline{\text{RSTIN}}$ pin is released, and after few CPU clock (Filter delay plus 3...8 TCL), the internal reset signal RST is released as well, so the code execution can start immediately after. Obviously, an eventual access to the data in internal Flash is forbidden before its initialization phase is completed: an eventual access during starting phase will return FFFFh (just at the beginning), while later 009Bh (an illegal opcode trap can be generated).

At Power-on, the $\overline{\text{RSTIN}}$ pin shall be tied low for a minimum time that includes also the start-up time of the main oscillator ($t_{\text{STUP}} = 1\text{ms}$ for resonator, 10ms for crystal) and PLL synchronization time ($t_{\text{PSUP}} = 200\mu\text{s}$): this means that if the internal FLASH is used, the $\overline{\text{RSTIN}}$ pin could be released before the main oscillator and PLL are stable to recover some time in the start-up phase (FLASH initialization only needs stable V_{18} , but does not need stable system clock since an internal dedicated oscillator is used).

Warning: It is recommended to provide the external hardware with a current limitation circuitry. This is necessary to avoid permanent damages of the device during the power-on transient, when the capacitance on V₁₈ pin is charged. For the on-chip voltage regulator functionality 10nF are sufficient: anyway, a maximum of 100nF on V₁₈ pin should not generate problems of over-current (higher value is allowed if current is limited by the external hardware). External current limitation is anyway recommended also to avoid risks of damage in case of temporary short between V₁₈ and ground: the internal 1.8V drivers are sized to drive currents of several tens of Ampere, so the current shall be limited by the external hardware. The limit of current is imposed by power dissipation considerations (Refer to Electrical Characteristics Section).

In [Figure 16](#) and [Figure 17](#) Asynchronous Power-on timing diagrams are reported, respectively with boot from internal or external memory, highlighting the reset phase extension introduced by the embedded FLASH module when selected.

Note: Never power the device without keeping \overline{RSTIN} pin grounded: the device could enter in unpredictable states, risking also permanent damages.

Figure 16. Asynchronous power-on RESET ($\overline{EA} = 1$)

Figure 17. Asynchronous power-on RESET ($\overline{EA} = 0$)

1. 3 to 8 TLC depending on clock source selection.

Hardware reset

The asynchronous reset must be used to recover from catastrophic situations of the application. It may be triggered by the hardware of the application. Internal hardware logic and application circuitry are described in [Section 20.7: Reset circuitry](#) and [Figure 29](#), [Figure 30](#) and [Figure 31](#). It occurs when \overline{RSTIN} is low and RPD is detected (or becomes) low as well.

Figure 18. Asynchronous hardware RESET ($\overline{EA} = 1$)

1. Longer than Port0 settling time + PLL synchronization (if needed, that is P0 (15:13) changed).
2. Longer than 500ns to take into account of Input Filter on RSTIN pin.

Figure 19. Asynchronous hardware RESET ($\overline{EA} = 0$)

1. Longer than Port0 settling time + PLL synchronization (if needed, that is P0(15:13) changed)
Longer than 500ns to take into account of Input Filter on RSTIN pin
2. 3 to 8 TCL depending on clock source selection.

Exit from asynchronous reset state

When the \overline{RSTIN} pin is pulled high, the device restarts: as already mentioned, if internal FLASH is used, the restarting occurs after the embedded FLASH initialization routine is completed. The system configuration is latched from Port0: ALE, \overline{RD} and $\overline{WR/WRL}$ pins are driven to their inactive level. The ST10F272 starts program execution from memory location 00'0000h in code segment 0. This starting location will typically point to the general initialization routine. Timing of asynchronous Hardware Reset sequence are summarized in [Figure 18](#) and [Figure 19](#).

20.3 Synchronous reset (warm reset)

A synchronous reset is triggered when \overline{RSTIN} pin is pulled low while RPD pin is at high level. In order to properly activate the internal reset logic of the device, the RSTIN pin must be held low, at least, during 4 TCL (2 periods of CPU clock): refer also to [Section 20.1](#) for details on minimum reset pulse duration. The I/O pins are set to high impedance and RSTOUT pin is driven low. After RSTIN level is detected, a short duration of a maximum of 12 TCL (six periods of CPU clock) elapses, during which pending internal hold states are cancelled and the current internal access cycle if any is completed. External bus cycle is aborted. The internal pull-down of RSTIN pin is activated if bit BDRSTEN of SYSCON register was previously set by software. Note that this bit is always cleared on power-on or after a reset sequence.

Short and long synchronous reset

Once the first maximum 16 TCL are elapsed (4+12TCL), the internal reset sequence starts. It is 1024 TCL cycles long: at the end of it, and after other 8TCL the level of $\overline{\text{RSTIN}}$ is sampled (after the filter, see $\overline{\text{RSTF}}$ in the drawings): if it is already at high level, only Short Reset is flagged (Refer to [Section 19](#) for details on reset flags); if it is recognized still low, the Long reset is flagged as well. The major difference between Long and Short reset is that during the Long reset, also P0(15:13) become transparent, so it is possible to change the clock options.

Warning: In case of a short pulse on $\overline{\text{RSTIN}}$ pin, and when Bidirectional reset is enabled, the $\overline{\text{RSTIN}}$ pin is held low by the internal circuitry. At the end of the 1024 TCL cycles, the $\overline{\text{RSTIN}}$ pin is released, but due to the presence of the input analog filter the internal input reset signal ($\overline{\text{RSTF}}$ in the drawings) is released later (from 50 to 500ns). This delay is in parallel with the additional 8 TCL, at the end of which the internal input reset line ($\overline{\text{RSTF}}$) is sampled, to decide if the reset event is Short or Long. In particular:

- If 8 TCL > 500ns ($F_{\text{CPU}} < 8 \text{ MHz}$), the reset event is always recognized as Short
- If 8 TCL < 500ns ($F_{\text{CPU}} > 8 \text{ MHz}$), the reset event could be recognized either as Short or Long, depending on the real filter delay (between 50 and 500ns) and the CPU frequency ($\overline{\text{RSTF}}$ sampled High means Short reset, $\overline{\text{RSTF}}$ sampled Low means Long reset). Note that in case a Long Reset is recognized, once the 8 TCL are elapsed, the P0 (15:13) pins becomes transparent, so the system clock can be re-configured. The port returns not transparent 3-4TCL after the internal $\overline{\text{RSTF}}$ signal becomes high.

The same behavior just described, occurs also when unidirectional reset is selected and $\overline{\text{RSTIN}}$ pin is held low till the end of the internal sequence (exactly 1024TCL + max 16 TCL) and released exactly at that time.

Note: When running with CPU frequency lower than 40 MHz, the minimum valid reset pulse to be recognized by the CPU (4 TCL) could be longer than the minimum analog filter delay (50ns); so it might happen that a short reset pulse is not filtered by the analog input filter, but on the other hand it is not long enough to trigger a CPU reset (shorter than 4 TCL): this would generate a FLASH reset but not a system reset. In this condition, the FLASH answers always with FFFFh, which leads to an illegal opcode and consequently a trap event is generated.

Exit from synchronous reset state

The reset sequence is extended until $\overline{\text{RSTIN}}$ level becomes high. Besides, it is internally prolonged by the FLASH initialization when $\overline{\text{EA}}=1$ (internal memory selected). Then, the code execution restarts. The system configuration is latched from Port0, and ALE, $\overline{\text{RD}}$ and $\overline{\text{WR}}$ / $\overline{\text{WRL}}$ pins are driven to their inactive level. The ST10F272 starts program execution from memory location 00'0000h in code segment 0. This starting location will typically point to the general initialization routine. Timing of synchronous reset sequence are summarized in [Figure 20](#) and [Figure 21](#) where a Short Reset event is shown, with particular highlighting on the fact that it can degenerate into Long Reset: the two figures show the behavior when booting from internal or external memory respectively. [Figure 22](#) and [Figure 23](#) reports the

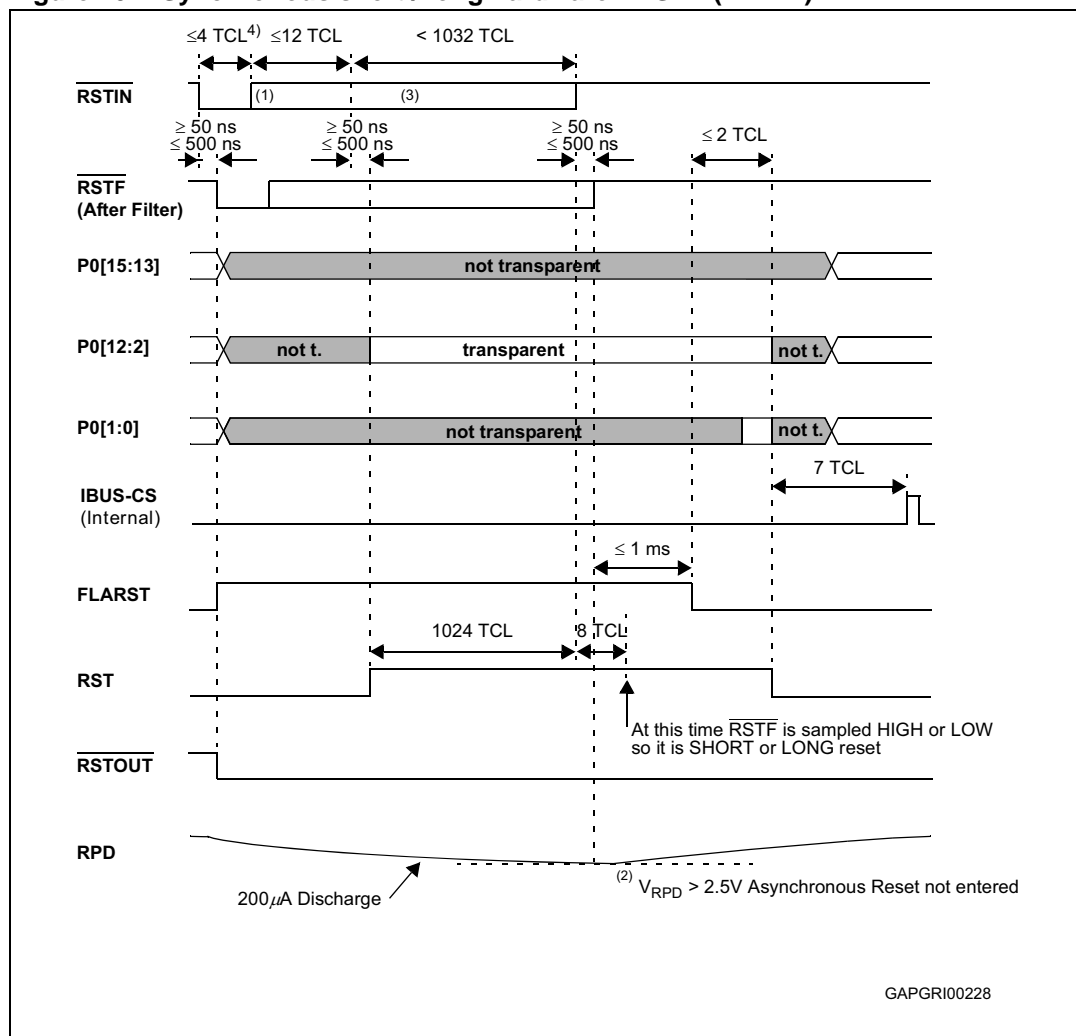

timing of a typical synchronous Long Reset, again when booting from internal or external memory.

Synchronous reset and RPD pin

Whenever the $\overline{\text{RSTIN}}$ pin is pulled low (by external hardware or as a consequence of a Bidirectional reset), the RPD internal weak pull-down is activated. The external capacitance (if any) on RPD pin is slowly discharged through the internal weak pull-down. If the voltage level on RPD pin reaches the input low threshold (around 2.5V), the reset event becomes immediately asynchronous. In case of hardware reset (short or long) the situation goes immediately to the one illustrated in [Figure 18](#). There is no effect if RPD comes again above the input threshold: the asynchronous reset is completed coherently. To grant the normal completion of a synchronous reset, the value of the capacitance shall be big enough to maintain the voltage on RPD pin sufficient high along the duration of the internal reset sequence.

For a Software or Watchdog reset events, an active synchronous reset is completed regardless of the RPD status.

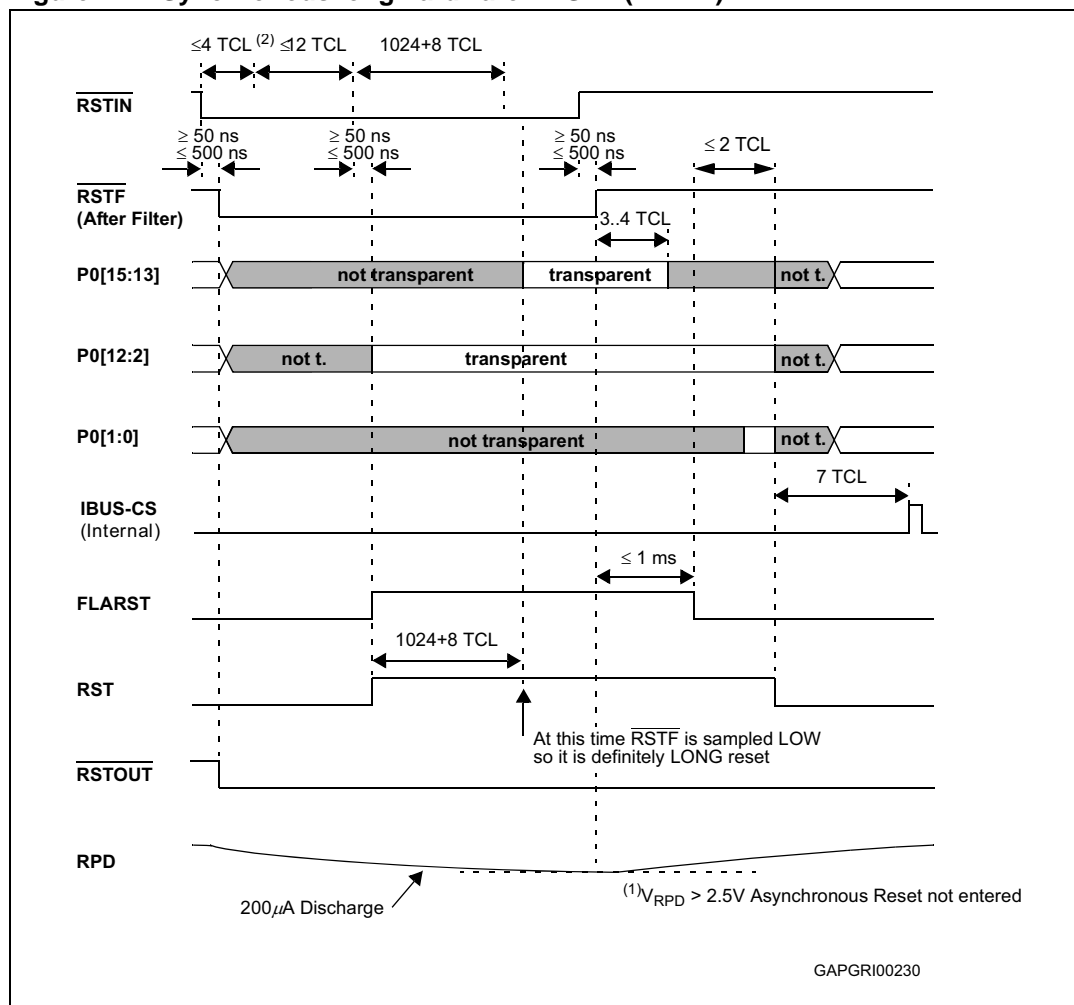

It is important to highlight that the signal that makes RPD status transparent under reset is the internal RSTF (after the noise filter).

Figure 20. Synchronous short / long hardware RESET ($\overline{EA} = 1$)

1. RSTIN assertion can be released there. Refer also to [Section 21.1](#) for details on minimum pulse duration.
2. If during the reset condition (RSTIN low), RPD voltage drops below the threshold voltage (about 2.5 V for 5 V operation), the asynchronous reset is then immediately entered.
3. RSTIN pin is pulled low if bit BDRSTEN (bit 3 of SYSCON register) was previously set by software. Bit BDRSTEN is cleared after reset.
4. Minimum RSTIN low pulse duration shall also be longer than 500ns to guarantee the pulse is not masked by the internal filter (refer to [Section 21.1](#)).

Figure 21. Synchronous short / long hardware RESET ($\overline{EA} = 0$)

1. RSTIN assertion can be released there. Refer also to [Section 21.1](#) for details on minimum pulse duration.
2. If during the reset condition (RSTIN low), RPD voltage drops below the threshold voltage (about 2.5 V for 5 V operation), the asynchronous reset is then immediately entered.
3. 3 to 8 TCL depending on clock source selection.
4. RSTIN pin is pulled low if bit BDRSTEN (bit 3 of SYSCON register) was previously set by software. Bit BDRSTEN is cleared after reset.
5. Minimum RSTIN low pulse duration shall also be longer than 500ns to guarantee the pulse is not masked by the internal filter (refer to [Section 21.1](#)).

Figure 22. Synchronous long hardware RESET ($\overline{EA} = 1$)

1. If during the reset condition (\overline{RSTIN} low), RPD voltage drops below the threshold voltage (about 2.5V for 5V operation), the asynchronous reset is then immediately entered. Even if RPD returns above the threshold, the reset is definitively taken as asynchronous.
2. Minimum \overline{RSTIN} low pulse duration shall also be longer than 500ns to guarantee the pulse is not masked by the internal filter (refer to [Section 21.1](#)).

Figure 23. Synchronous long hardware RESET ($\overline{EA} = 0$)

1. If during the reset condition (RSTIN low), RPD voltage drops below the threshold voltage (about 2.5V for 5V operation), the asynchronous reset is then immediately entered.
2. Minimum RSTIN low pulse duration shall also be longer than 500ns to guarantee the pulse is not masked by the internal filter (refer to [Section 2.1.1](#)).
3. 3 to 8 TCL depending on clock source selection.

20.4 Software reset

A software reset sequence can be triggered at any time by the protected SRST (software reset) instruction. This instruction can be deliberately executed within a program, e.g. to leave bootstrap loader mode, or on a hardware trap that reveals system failure.

On execution of the SRST instruction, the internal reset sequence is started. The microcontroller behavior is the same as for a synchronous short reset, except that only bits P0.12...P0.8 are latched at the end of the reset sequence, while previously latched, bits P0.7...P0.2 are cleared (that is written at '1').

A Software reset is always taken as synchronous: there is no influence on Software Reset behavior with RPD status. In case Bidirectional Reset is selected, a Software Reset event pulls RSTIN pin low: this occurs only if RPD is high; if RPD is low, RSTIN pin is not pulled low even though Bidirectional Reset is selected.

Refer to [Figure 24](#) and [Figure 25](#) for unidirectional SW reset timing, and to [Figure 26](#), [Figure 27](#) and [Figure 28](#) for bidirectional.

20.5 Watchdog timer reset

When the watchdog timer is not disabled during the initialization, or serviced regularly during program execution, it overflows and trigger the reset sequence.

Unlike hardware and software resets, the watchdog reset completes a running external bus cycle if this bus cycle either does not use READY, or if READY is sampled active (low) after the programmed wait states.

When READY is sampled inactive (high) after the programmed wait states the running external bus cycle is aborted. Then the internal reset sequence is started.

Bit P0.12...P0.8 are latched at the end of the reset sequence and bit P0.7...P0.2 are cleared (that is written at '1').

A Watchdog reset is always taken as synchronous: there is no influence on Watchdog Reset behavior with RPD status. In case Bidirectional Reset is selected, a Watchdog Reset event pulls RSTIN pin low: this occurs only if RPD is high; if RPD is low, RSTIN pin is not pulled low even though Bidirectional Reset is selected.

Refer to [Figure 24](#) and [Figure 25](#) for unidirectional SW reset timing, and to [Figure 26](#), [Figure 27](#) and [Figure 28](#) for bidirectional.

Figure 24. SW / WDT unidirectional RESET ($\overline{EA} = 1$)

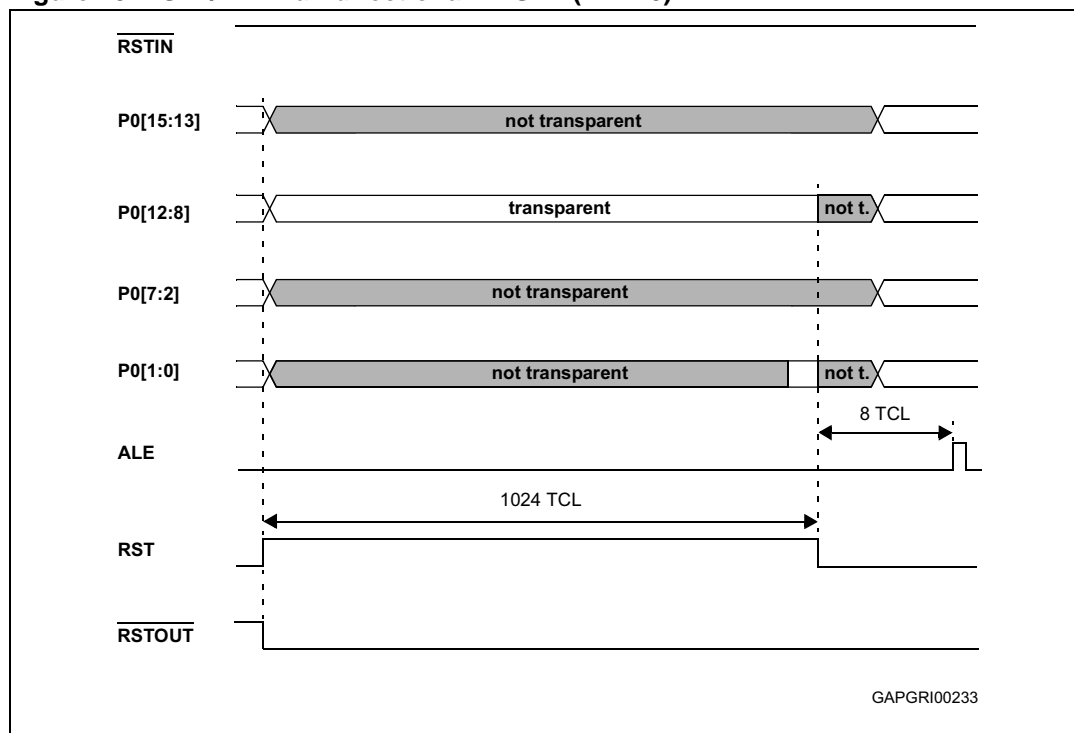

Figure 25. SW / WDT unidirectional RESET ($\overline{EA} = 0$)

20.6 Bidirectional reset

As shown in the previous sections, the \overline{RSTOUT} pin is driven active (low level) at the beginning of any reset sequence (synchronous/asynchronous hardware, software and watchdog timer resets). \overline{RSTOUT} pin stays active low beyond the end of the initialization routine, until the protected EINIT instruction (End of Initialization) is completed.

The Bidirectional Reset function is useful when external devices require a reset signal but cannot be connected to \overline{RSTOUT} pin, because \overline{RSTOUT} signal lasts during initialization. It is, for instance, the case of external memory running initialization routine before the execution of EINIT instruction.

Bidirectional reset function is enabled by setting bit 3 (BDRSTEN) in SYSCON register. It only can be enabled during the initialization routine, before EINIT instruction is completed.

When enabled, the open drain of the \overline{RSTIN} pin is activated, pulling down the reset signal, for the duration of the internal reset sequence (synchronous/asynchronous hardware, synchronous software and synchronous watchdog timer resets). At the end of the internal reset sequence the pull down is released and:

- After a Short Synchronous Bidirectional Hardware Reset, if \overline{RSTF} is sampled low 8 TCL periods after the internal reset sequence completion (refer to [Figure 20](#) and [Figure 21](#)), the Short Reset becomes a Long Reset. On the contrary, if \overline{RSTF} is sampled high the device simply exits reset state.
- After a Software or Watchdog Bidirectional Reset, the device exits from reset. If \overline{RSTF} remains still low for at least 4 TCL periods (minimum time to recognize a Short Hardware reset) after the reset exiting (refer to [Figure 26](#) and [Figure 27](#)), the Software

or Watchdog Reset become a Short Hardware Reset. On the contrary, if $\overline{\text{RSTF}}$ remains low for less than 4 TCL, the device simply exits reset state.

The Bidirectional reset is not effective in case RPD is held low, when a Software or Watchdog reset event occurs. On the contrary, if a Software or Watchdog Bidirectional reset event is active and RPD becomes low, the $\overline{\text{RSTIN}}$ pin is immediately released, while the internal reset sequence is completed regardless of RPD status change (1024 TCL).

Note: The bidirectional reset function is disabled by any reset sequence (bit BDRSTEN of SYSCON is cleared). To be activated again it must be enabled during the initialization routine.

WDTCN flags

Similarly to what already highlighted in the previous section when discussing about Short reset and the degeneration into Long reset, similar situations may occur when Bidirectional reset is enabled. The presence of the internal filter on $\overline{\text{RSTIN}}$ pin introduces a delay: when $\overline{\text{RSTIN}}$ is released, the internal signal after the filter (see $\overline{\text{RSTF}}$ in the drawings) is delayed, so it remains still active (low) for a while. It means that depending on the internal clock speed, a short reset may be recognized as a long reset: the WDTCN flags are set accordingly.

Besides, when either Software or Watchdog bidirectional reset events occur, again when the $\overline{\text{RSTIN}}$ pin is released (at the end of the internal reset sequence), the $\overline{\text{RSTF}}$ internal signal (after the filter) remains low for a while, and depending on the clock frequency it is recognized high or low: 8TCL after the completion of the internal sequence, the level of $\overline{\text{RSTF}}$ signal is sampled, and if recognized still low a Hardware reset sequence starts, and WDTCN will flag this last event, masking the previous one (Software or Watchdog reset). Typically, a Short Hardware reset is recognized, unless the $\overline{\text{RSTIN}}$ pin (and consequently internal signal $\overline{\text{RSTF}}$) is sufficiently held low by the external hardware to inject a Long Hardware reset. After this occurrence, the initialization routine is not able to recognize a Software or Watchdog bidirectional reset event, since a different source is flagged inside WDTCN register. This phenomenon does not occur when internal FLASH is selected during reset ($\text{EA} = 1$), since the initialization of the FLASH itself extend the internal reset duration well beyond the filter delay.

[Figure 26](#), [Figure 27](#) and [Figure 28](#) summarize the timing for Software and Watchdog Timer Bidirectional reset events: in particular [Figure 28](#) shows the degeneration into Hardware reset.

Figure 26. SW / WDT bidirectional RESET ($\overline{EA}=1$)

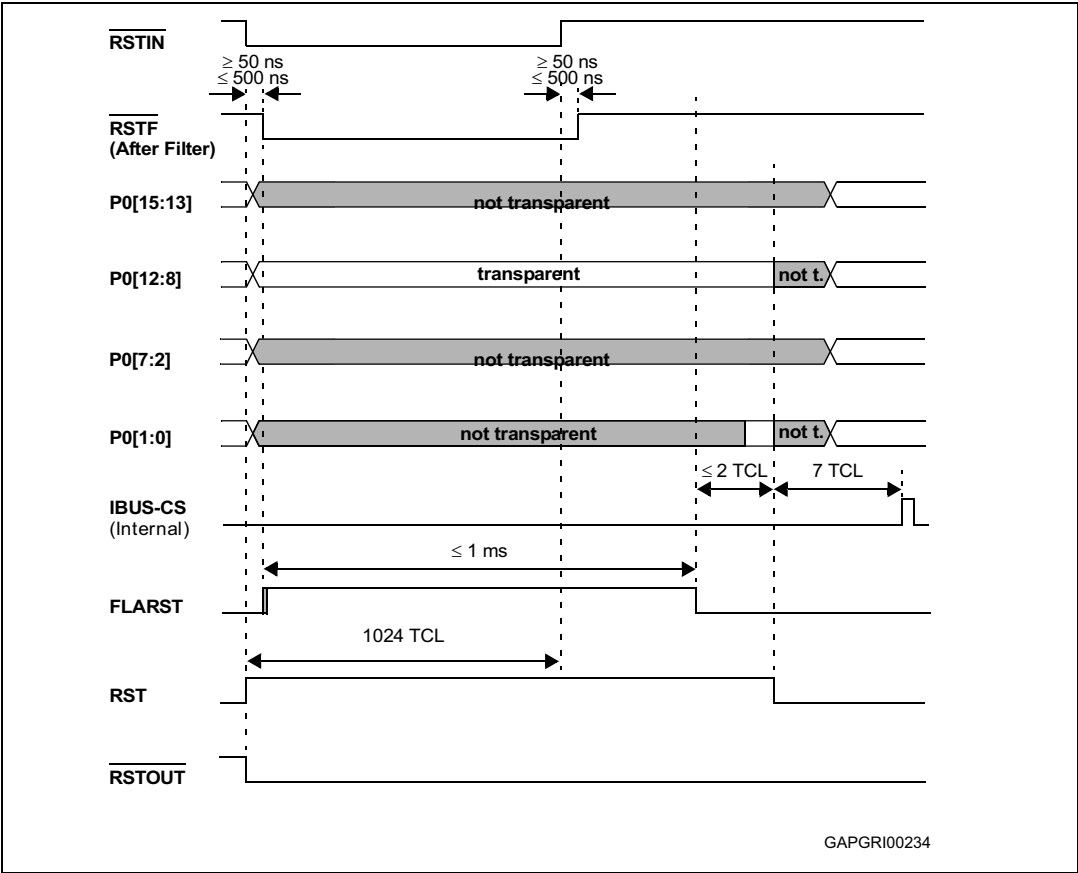

Figure 27. SW / WDT bidirectional RESET ($\overline{EA} = 0$)

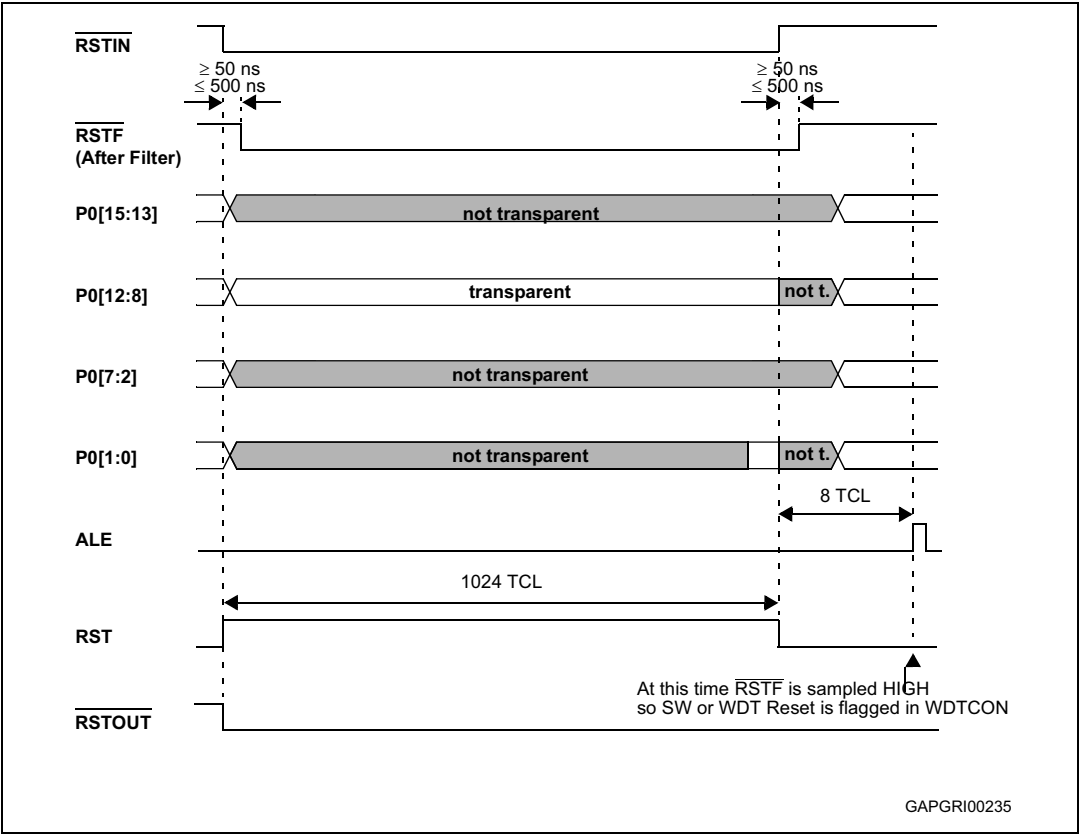

Figure 28. SW / WDT bidirectional RESET ($\overline{EA}=0$) followed by a HW RESET

20.7 Reset circuitry

Internal reset circuitry is described in [Figure 31](#). The \overline{RSTIN} pin provides an internal pull-up resistor of 50k Ω to 250k Ω (The minimum reset time must be calculated using the lowest value).

It also provides a programmable (BDRSTEN bit of SYSCON register) pull-down to output internal reset state signal (synchronous reset, watchdog timer reset or software reset).

This bidirectional reset function is useful in applications where external devices require a reset signal but cannot be connected to \overline{RSTOUT} pin.

This is the case of an external memory running codes before EINIT (end of initialization) instruction is executed. \overline{RSTOUT} pin is pulled high only when EINIT is executed.

The RPD pin provides an internal weak pull-down resistor which discharges external capacitor at a typical rate of 200 μ A. If bit PWDCFG of SYSCON register is set, an internal pull-up resistor is activated at the end of the reset sequence. This pull-up will charge any capacitor connected on RPD pin.

The simplest way to reset the ST10F272 is to insert a capacitor C1 between \overline{RSTIN} pin and V_{SS} , and a capacitor between \overline{RPD} pin and V_{SS} (C0) with a pull-up resistor R0 between \overline{RPD} pin and V_{DD} . The input \overline{RSTIN} provides an internal pull-up device equalling a resistor of 50k Ω to 250k Ω (the minimum reset time must be determined by the lowest value). Select C1 that produce a sufficient discharge time to permit the internal or external oscillator and / or internal PLL and the on-chip voltage regulator to stabilize.

1. It can degenerate into a Long Hardware Reset and consequently differently flagged (see [Section 20.3](#) for details).
2. When Bidirectional is active (and with RPD=0), it can be followed by a Short Hardware Reset and consequently differently flagged (see [Section 20.6](#) for details).

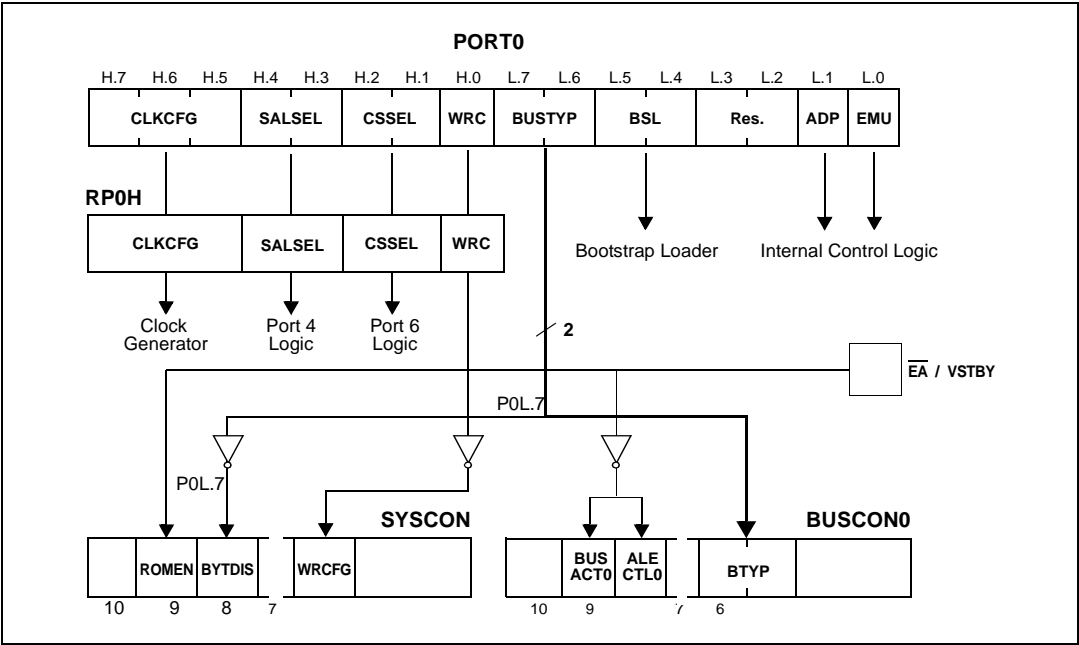

The start-up configurations and some system features are selected on reset sequences as described in [Table 51](#) and [Figure 34](#).

[Table 51](#) describes what is the system configuration latched on PORT0 in the six different reset modes. [Figure 34](#) summarizes the state of bits of PORT0 latched in RP0H, SYSCON, BUSCON0 registers.

Table 51. PORT0 latched configuration for the different reset events

| Sample event | PORT0 | | | | | | | | | | | | | | | |
|----------------------------------|---------------|-------|-------|-------|-------------------|-------|-------|--------------|-------|------------|----------|-------|----------|-------|----------|----------|

Figure 34. PORT0 bits latched into the different registers after reset

21 Power reduction modes

Three different power reduction modes with different levels of power reduction have been implemented in the ST10F272. In Idle mode only CPU is stopped, while peripheral still operate. In Power Down mode both CPU and peripherals are stopped. In Stand-by mode the main power supply (V_{DD}) can be turned off while a portion of the internal RAM remains powered via V_{STBY} dedicated power pin.

Idle and Power Down modes are software activated by a protected instruction and are terminated in different ways as described in the following sections.

Stand-by mode is entered simply removing V_{DD} , holding the MCU under reset state.

*Note: All external bus actions are completed before Idle or Power Down mode is entered. However, Idle or Power Down mode is **not** entered if READY is enabled, but has not been activated (driven low for negative polarity, or driven high for positive polarity) during the last bus access.*

21.1 Idle mode

Idle mode is entered by running IDLE protected instruction. The CPU operation is stopped and the peripherals still run.

Idle mode is terminate by any interrupt request. Whatever the interrupt is serviced or not, the instruction following the IDLE instruction will be executed after return from interrupt (RETI) instruction, then the CPU resumes the normal program.

21.2 Power down mode

Power Down mode starts by running PWRDN protected instruction. Internal clock is stopped, all MCU parts are on hold including the watchdog timer. The only exception could be the Real Time Clock if opportunely programmed and one of the two oscillator circuits as a consequence (either the main or the 32 kHz on-chip oscillator).

When Real Time Clock module is used, when the device is in Power Down mode a reference clock is needed. In this case, two possible configurations may be selected by the user application according to the desired level of power reduction:

- A 32 kHz crystal is connected to the on-chip low-power oscillator (pins XTAL3 / XTAL4) and running. In this case the main oscillator is stopped when Power Down mode is entered, while the Real Time Clock continue counting using 32 kHz clock signal as reference. The presence of a running low-power oscillator is detected after the Power-on: this clock is immediately assumed (if present, or as soon as it is detected) as reference for the Real Time Clock counter and it will be maintained forever (unless specifically disabled via software).
- Only the main oscillator is running (XTAL1 / XTAL2 pins). In this case the main oscillator is not stopped when Power Down is entered, and the Real Time Clock continue counting using the main oscillator clock signal as reference.

There are two different operating Power Down modes: protected mode and interruptible mode.

Before entering Power Down mode (by executing the instruction PWRDN), bit VREGOFF in XMISC register must be set.

Note: Leaving the main voltage regulator active during Power Down may lead to unexpected behavior (ex: CPU wake-up) and power consumption higher than what specified.

21.2.1 Protected power down mode

This mode is selected when PWDCFG (bit 5) of SYSCON register is cleared. The Protected Power Down mode is only activated if the NMI pin is pulled low when executing PWRDN instruction (this means that the PWRD instruction belongs to the NMI software routine). This mode is only deactivated with an external hardware reset on RSTIN pin.

21.2.2 Interruptible power down mode

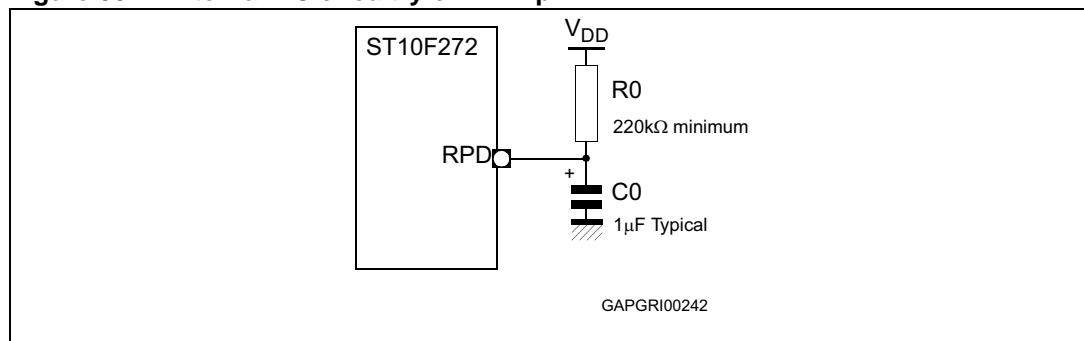

This mode is selected when PWDCFG (bit 5) of SYSCON register is set.

The Interruptible Power Down mode is only activated if all the enabled Fast External Interrupt pins are in their inactive level.

This mode is deactivated with an external reset applied to $\overline{\text{RSTIN}}$ pin or with an interrupt request applied to one of the Fast External Interrupt pins, or with an interrupt generated by the Real Time Clock, or with an interrupt generated by the activity on CAN's and I²C module interfaces. To allow the internal PLL and clock to stabilize, the $\overline{\text{RSTIN}}$ pin must be held low according the recommendations described in [Section 20](#).

An external RC circuit must be connected to RPD pin, as shown in the [Figure 35](#).

Figure 35. External RC circuitry on RPD pin

To exit Power Down mode with an external interrupt, an EXxIN (x = 7...0) pin has to be asserted for at least 40ns.

21.3 Stand-by mode

In Stand-by mode, it is possible to turn off the main V_{DD} provided that V_{STBY} is available through the dedicated pin of the ST10F272.

To enter Stand-by mode it is mandatory to held the device under reset: once the device is under reset, the RAM is disabled (see XRAM2EN bit of XPERCON register), and its digital interface is frozen in order to avoid any kind of data corruption.

A dedicated embedded low-power voltage regulator is implemented to generate the internal low voltage supply (about 1.65V in Stand-by mode) to bias all those circuits that shall remain

active: the portion of XRAM (16Kbytes for ST10F272E), the RTC counters and 32 kHz on-chip oscillator amplifier.

In normal running mode (that is when main V_{DD} is on) the V_{STBY} pin can be tied to V_{SS} during reset to exercise the EA functionality associated with the same pin: the voltage supply for the circuitries which are usually biased with V_{STBY} (see in particular the 32 kHz oscillator used in conjunction with Real Time Clock module), is granted by the active main V_{DD} .

It must be noted that Stand-by Mode can generate problems associated with the usage of different power supplies in CMOS systems; particular attention must be paid when the ST10F272 I/O lines are interfaced with other external CMOS integrated circuits: if V_{DD} of ST10F272 becomes (for example in Stand-by Mode) lower than the output level forced by the I/O lines of these external integrated circuits, the ST10F272 could be directly powered through the inherent diode existing on ST10F272 output driver circuitry. The same is valid for ST10F272 interfaced to active/inactive communication buses during Stand-by mode: current injection can be generated through the inherent diode.

Furthermore, the sequence of turning on/off of the different voltage could be critical for the system (not only for the ST10F272 device). The device Stand-by mode current (I_{STBY}) may vary while V_{DD} to V_{STBY} (and vice versa) transition occurs: some current flows between V_{DD} and V_{STBY} pins. System noise on both V_{DD} and V_{STBY} can contribute to increase this phenomenon.

21.3.1 Entering stand-by mode

As already said, to enter Stand-by Mode XRAM2EN bit in the XPERCON Register must be cleared: this allows to freeze immediately the RAM interface, avoiding any data corruption. As a consequence of a RESET event, the RAM Power Supply is switched to the internal low-voltage supply V_{18SB} (derived from V_{STBY} through the low-power voltage regulator). The RAM interface will remain frozen until the bit XRAM2EN is set again by software initialization routine (at next exit from main V_{DD} power-on reset sequence).

Since V_{18} is falling down (as a consequence of V_{DD} turning off), it can happen that the XRAM2EN bit is no longer able to guarantee its content (logic "0"), being the XPERCON Register powered by internal V_{18} . This does not generate any problem, because the Stand-by Mode switching dedicated circuit continues to confirm the RAM interface freezing, irrespective the XRAM2EN bit content; XRAM2EN bit status is considered again when internal V_{18} comes back over internal stand-by reference V_{18SB} .

If internal V_{18} becomes lower than internal stand-by reference (V_{18SB}) of about 0.3 to 0.45V with bit XRAM2EN set, the RAM Supply switching circuit is not active: in case of a temporary drop on internal V_{18} voltage versus internal V_{18SB} during normal code execution, no spurious Stand-by Mode switching can occur (the RAM is not frozen and can still be accessed).

The ST10F272 Core module, generating the RAM control signals, is powered by internal V_{18} supply; during turning off transient these control signals follow the V_{18} , while RAM is switched to V_{18SB} internal reference. It could happen that a high level of RAM write strobe from ST10F272 Core (active low signal) is low enough to be recognized as a logic "0" by the RAM interface (due to V_{18} lower than V_{18SB}): The bus status could contain a valid address for the RAM and an unwanted data corruption could occur. For this reason, an extra interface, powered by the switched supply, is used to prevent the RAM from this kind of potential corruption mechanism.

Warning: During power-off phase, it is important that the external hardware maintains a stable ground level on RSTIN pin, without any glitch, in order to avoid spurious exiting from reset status with unstable power supply.

21.3.2 Exiting stand-by mode

After the system has entered the Stand-by Mode, the procedure to exit this mode consists of a standard power-on sequence, with the only difference that the RAM is already powered through V_{18SB} internal reference (derived from V_{STBY} pin external voltage).

It is recommended to held the device under RESET (RSTIN pin forced low) until external VDD voltage pin is stable. Even though, at the very beginning of the power-on phase, the device is maintained under reset by the internal low voltage detector circuit (implemented inside the main voltage regulator) till the internal V18 becomes higher than about 1.0V, there is no warranty that the device stays under reset status if RSTIN is at high level during power ramp up. So, it is important the external hardware is able to guarantee a stable ground level on RSTIN along the power-on phase, without any temporary glitch.

The external hardware shall be responsible to drive low the RSTIN pin until the VDD is stable, even though the internal LVD is active.

Once the internal reset signal goes low, the RAM (still frozen) power supply is switched to the main V_{18} .

At this time, everything becomes stable, and the execution of the initialization routines can start: XRAM2EN bit can be set, enabling the RAM.

21.3.3 Real time clock and stand-by mode

When stand-by mode is entered (turning off the main supply V_{DD}), the Real Time Clock counting can be maintained running in case the on-chip 32 kHz oscillator is used to provide the reference to the counter. This is not possible if the main oscillator is used as reference for the counter: Being the main oscillator powered by V_{DD} , once this is switched off, the oscillator is stopped.

21.3.4 Power reduction modes summary

In [Table 52](#), a summary of the different power reduction modes is reported.

Table 52. Power reduction modes summary

| Mode | V _{DD} | V _{STBY} | CPU | Peripherals | RTC | Main OSC | 32 kHz OSC | STBY XRAM | XRAM |
|------------|-----------------|-------------------|-----|-------------|-----|----------|------------|-----------|--------|
| Idle | on | on | off | on | off | run | off | biased | biased |
| | on | on | off | on | on | run | on | biased | biased |
| Power down | on | on | off | off | off | off | off | biased | biased |
| | on | on | off | off | on | on | off | biased | biased |
| | on | on | off | off | on | off | on | biased | biased |
| Stand-by | off | on | off | off | off | off | off | biased | off |
| | off | on | off | off | on | off | on | biased | off |

22 Programmable output clock divider

A specific register mapped on the XBUS allows to choose the division factor on the CLKOUT signal (P3.15). This register is mapped on X-Miscellaneous memory address range.

When CLKOUT function is enabled by setting bit CLKEN of register SYSCON, by default the CPU clock is output on P3.15. Setting bit XMISCEN of register XPERCON and bit XPEN of register SYSCON, it is possible to program the clock prescaling factor: in this way on P3.15 a prescaled value of the CPU clock can be output.

When CLKOUT function is not enabled (bit CLKEN of register SYSCON cleared), P3.15 does not output any clock signal, even though XCLKOUTDIV register is programmed.

23 Register set

This section summarizes all registers implemented in the ST10F272, ordered by name.

23.1 Special function registers

[Table 25](#) lists all SFRs which are implemented in the ST10F272 in alphabetical order.

Bit-addressable SFRs are marked with the letter “b” in column “Name”.

SFRs within the **Extended SFR-Space** (ESFRs) are marked with the letter “E” in column “Physical Address”.

Table 53. List of special function registers

| Name | Physical address | 8-bit address | Description | Reset value |
|----------|------------------|---------------|--|-------------|
| ADCICb | FF98h | CCh | A/D converter end of conversion interrupt control register | --00h |
| ADCONb | FFA0h | D0h | A/D converter control register | 0000h |
| ADDAT | FEA0h | 50h | A/D converter result register | 0000h |
| ADDAT2 | F0A0hE | 50h | A/D converter 2 result register | 0000h |
| ADDRSEL1 | FE18h | 0Ch | Address select register 1 | 0000h |
| ADDRSEL2 | FE1Ah | 0Dh | Address select register 2 | 0000h |
| ADDRSEL3 | FE1Ch | 0Eh | Address select register 3 | 0000h |
| ADDRSEL4 | FE1Eh | 0Fh | Address select register 4 | 0000h |
| ADEICb | FF9Ah | CDh | A/D converter overrun error interrupt control register | --00h |
| BUSCON0b | FF0Ch | 86h | Bus configuration register 0 | 0xx0h |
| BUSCON1b | FF14h | 8Ah | Bus configuration register 1 | 0000h |
| BUSCON2b | FF16h | 8Bh | Bus configuration register 2 | 0000h |

| XP1ICb | F18EhE | C7h | See Section 9.1 | -- 00h ³⁾ |
| XP2ICb | F196hE | CBh | See Section 9.1 | -- 00h ³⁾ |
| XP3ICb | F19EhE | CFh | See Section 9.1 | -- 00h ³⁾ |

Table 53. List of special function registers (continued)

| Name | Physical address | 8-bit address | Description | Reset value |
|-----------|------------------|---------------|---|-------------|
| XPERRCONb | F024hE | 12h | XPERR configuration register | -- 05h |
| ZEROSb | FF1Ch | 8Eh | Constant value 0's register (read only) | 0000h |

Note:

1. The system configuration is selected during reset. SYSCON reset value is 0000 0xx0 x000 0000b.
2. Reset Value depends on different triggered reset event.
3. The XPnIC Interrupt Control Registers control interrupt requests from integrated X-Bus peripherals. Some software controlled interrupt requests may be generated by setting the XPnIR bits (of XPnIC register) of the unused X-Peripheral nodes.

23.2 X-registers

[Table 54](#) lists all X-Bus registers which are implemented in the ST10F272 ordered by their name. The FLASH control registers are listed in a separate section, in spite of they also are physically mapped on X-Bus memory space.

Note: The X-Registers are not bit-addressable.

Table 54. List of XBus registers

| Name | Physical address | Description | Reset value |
|------------|------------------|------------------------------|-------------|
| CAN1BRPER | EF0Ch | CAN1: BRP extension register | 0000h |
| CAN1BTR | EF06h | CAN1: Bit timing register | 2301h |
| CAN1CR | EF00h | CAN1: CAN control register | 0001h |
| CAN1EC | EF04h | CAN1: error counter | 0000h |
| CAN1IF1A1 | EF18h | CAN1: IF1 arbitration 1 | 0000h |
| CAN1IF1A2 | EF1Ah | CAN1: IF1 arbitration 2 | 0000h |
| CAN1IF1CM | EF12h | CAN1: IF1 command mask | 0000h |
| CAN1IF1CR | EF10h | CAN1: IF1 command request | 0001h |
| CAN1IF1DA1 | EF1Eh | CAN1: IF1 data A 1 | 0000h |
| CAN1IF1DA2 | EF20h | CAN1: IF1 data A 2 | 0000h |
| CAN1IF1DB1 | EF22h | CAN1: IF1 data B 1 | 0000h |
| CAN1IF1DB2 | EF24h | CAN1: IF1 data B 2 | 0000h |
| CAN1IF1M1 | EF14h | CAN1: IF1 mask 1 | FFFFh |
| CAN1IF1M2 | EF16h | CAN1: IF1 mask 2 | FFFFh |
| CAN1IF1MC | EF1Ch | CAN1: IF1 message control | 0000h |
| CAN1IF2A1 | EF48h | CAN1: IF2 arbitration 1 | 0000h |
| CAN1IF2A2 | EF4Ah | CAN1: IF2 arbitration 2 | 0000h |

Table 54. List of XBus registers (continued)

| Name | Physical address | Description | Reset value |
|------------|------------------|------------------------------|-------------|
| CAN1IF2CM | EF42h | CAN1: IF2 command mask | 0000h |
| CAN1IF2CR | EF40h | CAN1: IF2 command request | 0001h |
| CAN1IF2DA1 | EF4Eh | CAN1: IF2 data A 1 | 0000h |
| CAN1IF2DA2 | EF50h | CAN1: IF2 data A 2 | 0000h |
| CAN1IF2DB1 | EF52h | CAN1: IF2 data B 1 | 0000h |
| CAN1IF2DB2 | EF54h | CAN1: IF2 data B 2 | 0000h |

23.3 Flash registers ordered by name

[Table 55](#) lists all Flash Control Registers which are implemented in the ST10F272 ordered by their name. These registers are physically mapped on the IBus, except for XFVTAUR0, which is mapped on XBus. Note that these registers are not bit-addressable.

Table 55. List of flash registers

| Name | Physical address | Description | Reset value |
|----------|------------------|--|-------------|
| FARH | 0x0008 0012 | Flash address register - high | 0000h |
| FARL | 0x0008 0010 | Flash address register - low | 0000h |
| FCR0H | 0x0008 0002 | Flash control register 0 - high | 0000h |
| FCR0L | 0x0008 0000 | Flash control register 0 - low | 0000h |
| FCR1H | 0x0008 0006 | Flash control register 1 - high | 0000h |
| FCR1L | 0x0008 0004 | Flash control register 1 - low | 0000h |
| FDR0H | 0x0008 000A | Flash data register 0 - high | FFFFh |
| FDR0L | 0x0008 0008 | Flash data register 0 - low | FFFFh |
| FDR1H | 0x0008 000E | Flash data register 1 - high | FFFFh |
| FDR1L | 0x0008 000C | Flash data register 1 - low | FFFFh |
| FER | 0x0008 0014 | Flash error register | 0000h |
| FNVAPR0 | 0x0008 DFB8 | Flash non volatile access protection reg.0 | ACFFh |
| FNVAPR1H | 0x0008 DFBE | Flash non volatile access protection reg.1 - high | FFFFh |
| FNVAPR1L | 0x0008 DFBC | Flash non volatile access protection reg.1 - low | FFFFh |
| FNVWPIR | 0x0008 DFB0 | Flash non volatile protection I register | FFFFh |
| XFVTAUR0 | 0x0000 EB50 | XBus Flash volatile temporary access unprotection register 0 | 0000h |

23.4 Identification registers

The ST10F272 have four Identification registers, mapped in ESFR space. These registers contain:

- A manufacturer identifier
- A chip identifier with its revision
- A internal Flash and size identifier
- Programming voltage description

| IDMANUF (F07Eh / 3Fh) | | | | | | | | ESFR | | | | Reset Value: 0403h | | | |
|-----------------------|----|----|----|----|----|---|---|------|---|---|---|--------------------|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| MANUF | | | | | | | | | | | 0 | 0 | 0 | 1 | 1 |
| R | | | | | | | | | | | R | | | | |

Table 56. IDMANUF

| Bit | Function |
|-------|--|
| MANUF | Manufacturer identifier 020h: STMicroelectronics manufacturer (JTAG worldwide normalization). |

| IDCHIP (F07Ch / 3Eh) | | | | | | | | ESFR | | | | Reset Value: 110Xh | | | |
|----------------------|----|----|----|----|----|---|---|------|---|---|-------|--------------------|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| IDCHIP | | | | | | | | | | | REVID | | | | |
| R | | | | | | | | | | | R | | | | |

Table 57. IDCHIP

| Bit | Function |
|--------|---|
| IDCHIP | Device identifier 110h: ST10F272 identifier (272). |
| REVID | Device revision identifier Xh: According to revision number. |

| IDMEM (F07Ah / 3Dh) | | | | | | | | ESFR | | | | Reset Value: 3040h | | | |
|---------------------|----|----|----|---------|----|---|---|------|---|---|---|--------------------|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| MEMTYP | | | | MEMSIZE | | | | | | | | | | | |
| R | | | | R | | | | | | | | | | | |

Table 58. IDMEM

| Bit | Function |
|---------|--|
| MEMSIZE | Internal memory size Internal memory size is 4 x (MEMSIZE) (in Kbyte) 040h for 256 Kbytes (ST10F272) |
| MEMTYP | Internal memory type '0h': ROM-Less '1h': (M) ROM memory '2h': (S) Standard Flash memory '3h': (H) High performance Flash memory (ST10F272) '4h...Fh': Reserved |

| IDPROG (F078h / 3Ch) | | | | | | | | ESFR | | | | Reset Value: 0040h | | | |
|----------------------|----|----|----|----|----|---|---|---------|---|---|---|--------------------|---|---|---|
| 15 | 14 | 13 | 12 | 11 | 10 | 9 | 8 | 7 | 6 | 5 | 4 | 3 | 2 | 1 | 0 |
| PROGVPP | | | | | | | | PROGVDD | | | | | | | |
| R | | | | | | | | R | | | | | | | |

Table 59. IDPROG

| Bit | Function |
|---------|--|
| PROGVDD | Programming V_{DD} voltage V_{DD} voltage when programming EPROM or FLASH devices is calculated using the following formula: $V_{DD} = 20 \times [\text{PROGVDD}] / 256$ (volts) - 40h for ST10F272 (5V). |
| PROGVPP | Programming V_{PP} voltage (no need of external V_{PP}) - 00h |

Note: All identification words are read only registers.

The values written inside different Identification Register bits are valid only after the Flash initialization phase is completed. When code execution is started from internal memory (pin \overline{EA} held high during reset), the Flash has certainly completed its initialization, so the bits of Identification Registers are immediately ready to be read out. On the contrary, when code execution is started from external memory (pin \overline{EA} held low during reset), the Flash initialization is not yet completed, so the bits of Identification Registers are not ready. The user can poll bits 15 and 14 of IDMEM register: when both bits are read low, the Flash initialization is complete, so all Identification Register bits are correct.

Before Flash initialization completion, the default setting of the different Identification Registers are the following:

- IDMANUF 0403h
- IDCHIP 110xh (x = silicon revision)
- IDMEM F040h
- IDPROG 0040h

24 Electrical characteristics

24.1 Absolute maximum ratings

Stressing the device above the rating listed in [Table 60](#) may cause permanent damage to the device. These are stress ratings only and operation of the device at these or any other conditions above those indicated in the Operating sections of this specification is not implied. Exposure to the conditions in [Table 60](#) for extended periods may affect device reliability. During overload conditions ($V_{IN} > V_{DD}$ or $V_{IN} < V_{SS}$) the voltage on pins with respect to ground (V_{SS}) must not exceed the values defined by the Absolute Maximum Ratings.

During Power-on and Power-off transients (including Standby entering/exiting phases), the relationships between voltages applied to the device and the main V_{DD} shall be always respected. In particular power-on and power-off of V_{AREF} shall be coherent with V_{DD} transient, in order to avoid undesired current injection through the on-chip protection diodes.

Table 60. Absolute maximum ratings

| Symbol | Parameter | Values | Unit |
|------------|--|------------------------|------|
| V_{DD} | Voltage on V_{DD} pins with respect to ground (V_{SS}) | -0.5 to +6.5 | V |
| V_{STBY} | Voltage on V_{STBY} pin with respect to ground (V_{SS}) | -0.5 to +6.5 | V |
| V_{AREF} | Voltage on V_{AREF} pins with respect to ground (V_{SS}) | -0.3 to V_{DD} | V |
| V_{AGND} | Voltage on V_{AGND} pins with respect to ground (V_{SS}) | V_{SS} | V |
| V_{IO} | Voltage on any pin with respect to ground (V_{SS}) | -0.5 to $V_{DD} + 0.5$ | V |
| I_{OV} | Input current on any pin during overload condition | ± 10 | mA |
| I_{TOV} | Absolute sum of all input currents during overload condition | 75 | mA |
| T_{ST} | Storage temperature | -65 to +150 | °C |
| ESD | ESD Susceptibility (Human Body Model) | 2000 | V |

24.2 Recommended operating conditions

Table 61. Recommended operating conditions

| Symbol | Parameter | Value | | Unit |
|-------------------|---|-------|------|------|
| | | Min | Max | |
| V _{DD} | Operating supply voltage | 4.5 | 5.5 | V |
| V _{STBY} | Operating stand-by supply voltage ⁽¹⁾ | 4.5 | 5.5 | V |
| V _{AREF} | Operating analog reference voltage ⁽²⁾ | | | |
| T _A | Ambient temperature under bias | -40 | +125 | °C |
| T _J | Junction temperature under bias | -40 | +150 | °C |

1. The value of the V_{STBY} voltage is specified in the range 4.5 - 5.5 Volt. Nevertheless, it is acceptable to exceed the upper limit (up to 6.0 Volt) for a maximum of 100 hours over the global 300000 hours, representing the lifetime of the device (about 30 years). On the other hand, it is possible to exceed the lower limit (down to 4.0 Volt) whenever RTC and 32kHz on-chip oscillator amplifier are turned off (only Stand-by RAM powered through VSTBY pin in Stand-by mode). When VSTBY voltage is lower than main VDD, the input section of VSTBY/EA pin can generate a spurious static consumption on VDD power supply (in the range of tenth of μ A).

2. For details on operating conditions concerning the usage of A/D Converter refer to [Section 24.7](#).

24.3 Power considerations

The average chip-junction temperature, T_J, in degrees Celsius, may be calculated using the following equation:

$$T_J = T_A + (P_D \times \Theta_{JA}) \quad (1)$$

Where:

T_A is the Ambient Temperature in °C,

Θ_{JA} is the Package Junction-to-Ambient Thermal Resistance, in °C/W,

P_D is the sum of P_{INT} and P_{I/O} (P_D = P_{INT} + P_{I/O}),

P_{INT} is the product of I_{DD} and V_{DD}, expressed in Watt. This is the Chip Internal Power,

P_{I/O} represents the Power Dissipation on Input and Output Pins; User Determined.

Most of the time for the applications P_{I/O} < P_{INT} and may be neglected. On the other hand, P_{I/O} may be significant if the device is configured to drive continuously external modules and/or memories.

An approximate relationship between P_D and T_J (if P_{I/O} is neglected) is given by:

$$P_D = K / (T_J + 273^\circ\text{C}) \quad (2)$$

Therefore (solving equations 1 and 2):

$$K = P_D \times (T_A + 273^\circ\text{C}) + \Theta_{JA} \times P_D^2 \quad (3)$$

Where:

K is a constant for the particular part, which may be determined from equation (3) by measuring P_D (at equilibrium) for a known T_A. Using this value of K, the values of P_D and T_J may be obtained by solving equations (1) and (2) iteratively for any value of T_A.

Table 62. Thermal characteristics

| Symbol | Description | Value (typical) | Unit |
|---------------|--|-----------------|------|
| Θ_{JA} | Thermal Resistance Junction-Ambient | | |
| | PQFP 144 - 28 x 28 x 3.4 mm / 0.65 mm pitch | 30 | °C/W |
| | LQFP 144 - 20 x 20 mm / 0.5 mm pitch | 40 | |
| | LQFP 144 - 20 x 20 mm / 0.5 mm pitch on four layer FR4 board (2 layers signals / 2 layers power) | 35 | |

Based on thermal characteristics of the package and with reference to the power consumption figures provided in next tables and diagrams, the following product classification can be proposed. Anyhow, the exact power consumption of the device inside the application must be computed according to different working conditions, thermal profiles, real thermal resistance of the system (including printed circuit board or other substrata), I/O activity, and so on.

Table 63. Package characteristics

| Package | Ambient temperature range | CPU frequency range |
|----------|---------------------------|---------------------|
| PQFP 144 | -40 / +125°C | 1 – 64MHz |
| LQFP 144 | -40 / +125°C | 1 – 40MHz |

24.4 Parameter interpretation

The parameters listed in the following tables represent the characteristics of the ST10F272 and its demands on the system.

Where the ST10F272 logic provides signals with their respective timing characteristics, the symbol “**CC**” for Controller Characteristics, is included in the “Symbol” column. Where the external system must provide signals with their respective timing characteristics to the ST10F272, the symbol “**SR**” for System Requirement, is included in the “Symbol” column.

24.5 DC characteristics

$V_{DD} = 5\text{ V} \pm 10\%$, $V_{SS} = 0\text{ V}$, $T_A = -40\text{ to }+125^\circ\text{C}$

Table 64. DC characteristics

| Parameter | Symbol | Limit values | | Unit | Test Condition |
|--|----------------------|--------------|--|------|---|
| | | min. | max. | | |
| Input low voltage (TTL mode) (except $\overline{\text{RSTIN}}$, $\overline{\text{EA}}$, $\overline{\text{NMI}}$, RPD, XTAL1, READY) | V_{IL} SR | - 0.3 | 0.8 | V | — |
| Input low voltage (CMOS mode) (except $\overline{\text{RSTIN}}$, $\overline{\text{EA}}$, $\overline{\text{NMI}}$, RPD, XTAL1, READY) | V_{ILS} SR | - 0.3 | $0.3 V_{DD}$ | V | — |
| Input low voltage $\overline{\text{RSTIN}}$, $\overline{\text{EA}}$, $\overline{\text{NMI}}$, RPD | V_{IL1} SR | - 0.3 | $0.3 V_{DD}$ | V | — |
| Input low voltage XTAL1 (CMOS only) | V_{IL2} SR | - 0.3 | $0.3 V_{DD}$ | V | Direct Drive mode |
| Input low voltage READY (TTL only) | V_{IL3} SR | - 0.3 | 0.8 | V | — |
| Input high voltage (TTL mode) (except $\overline{\text{RSTIN}}$, $\overline{\text{EA}}$, $\overline{\text{NMI}}$, RPD, XTAL1) | V_{IH} SR | 2.0 | $V_{DD} + 0.3$ | V | — |
| Input high voltage (CMOS mode) (except $\overline{\text{RSTIN}}$, $\overline{\text{EA}}$, $\overline{\text{NMI}}$, RPD, XTAL1) | V_{IHS} SR | $0.7 V_{DD}$ | $V_{DD} + 0.3$ | V | — |
| Input high voltage $\overline{\text{RSTIN}}$, $\overline{\text{EA}}$, $\overline{\text{NMI}}$, RPD | V_{IH1} SR | $0.7 V_{DD}$ | $V_{DD} + 0.3$ | V | — |
| Input high voltage XTAL1 (CMOS only) | V_{IH2} SR | $0.7 V_{DD}$ | $V_{DD} + 0.3$ | V | Direct Drive mode |
| Input high voltage READY (TTL only) | V_{IH3} SR | 2.0 | $V_{DD} + 0.3$ | V | — |
| Input Hysteresis (TTL mode) (except $\overline{\text{RSTIN}}$, $\overline{\text{EA}}$, $\overline{\text{NMI}}$, XTAL1, RPD) | V_{HYS} CC | 400 | 700 | mV | (1) |
| Input Hysteresis (CMOS mode) (except $\overline{\text{RSTIN}}$, $\overline{\text{EA}}$, $\overline{\text{NMI}}$, XTAL1, RPD) | V_{HYSS} CC | 750 | 1400 | mV | (1) |
| Input Hysteresis $\overline{\text{RSTIN}}$, $\overline{\text{EA}}$, $\overline{\text{NMI}}$ | V_{HYS1} CC | 750 | 1400 | mV | (1) |
| Input Hysteresis XTAL1 | V_{HYS2} CC | 0 | 50 | mV | (1) |
| Input Hysteresis READY (TTL only) | V_{HYS3} CC | 400 | 700 | mV | (1) |
| Input Hysteresis RPD | V_{HYS4} CC | 500 | 1500 | mV | (1) |
| Output low voltage (P6[7:0], ALE, RD, WR/WRL, BHE/WRH, CLKOUT, $\overline{\text{RSTIN}}$, $\overline{\text{RSTOUT}}$) | V_{OL} CC | — | 0.4 0.05 | V | $I_{OL} = 8\text{ mA}$ $I_{OL} = 1\text{ mA}$ |
| Output low voltage (P0[15:0], P1[15:0], P2[15:0], P3[15,13:0], P4[7:0], P7[7:0], P8[7:0]) | V_{OL1} CC | — | 0.4 0.05 | V | $I_{OL1} = 4\text{ mA}$ $I_{OL1} = 0.5\text{ mA}$ |
| Output low voltage RPD | V_{OL2} CC | — | V_{DD} $0.5 V_{DD}$ $0.3 V_{DD}$ | V | $I_{OL2} = 85\text{ }\mu\text{A}$ $I_{OL2} = 80\text{ }\mu\text{A}$ $I_{OL2} = 60\text{ }\mu\text{A}$ |

Table 64. DC characteristics (continued)

| Parameter | Symbol | Limit values | | Unit | Test Condition |
|---|---------------------------------|---|--------------------------------|---------------|--|
| | | min. | max. | | |
| Output high voltage (P6[7:0], ALE, $\overline{\text{RD}}$, $\overline{\text{WR}}$ /WRL, $\overline{\text{BHE}}$ /WRH, CLKOUT, $\overline{\text{RSTOUT}}$) | V_{OH} CC | $V_{\text{DD}} - 0.8$ $V_{\text{DD}} - 0.08$ | – | V | $I_{\text{OH}} = -8 \text{ mA}$ $I_{\text{OH}} = -1 \text{ mA}$ |

- Not 100% tested, guaranteed by design characterization.
- This specification is not valid for outputs which are switched to open drain mode. In this case the respective output will float and the voltage is imposed by the external circuitry.
- Port 5 leakage values are granted for not selected A/D Converter channel. One channels is always selected (by default, after reset, P5.0 is selected). For the selected channel the leakage value is similar to that of other port pins.
- The leakage of P2.0 is higher than other pins due to the additional logic (pass gates active only in specific test modes) implemented on input path. Pay attention to not stress P2.0 input pin with negative overload beyond the specified limits: failures in Flash reading may occur (sense amplifier perturbation). Refer to next [Figure 36](#) for a scheme of the input circuitry.
- Overload conditions occur if the standard operating conditions are exceeded, i.e. the voltage on any pin exceeds the specified range (i.e. V_{OV} > V_{DD} + 0.3 V or V_{OV} < –0.3 V). The absolute sum of input overload currents on all port pins may not exceed 50mA. The supply voltage must remain within the specified limits.
- This specification is only valid during Reset, or during Hold- or Adapt-mode. Port 6 pins are only affected, if they are used for CS output and the open drain function is not enabled.
- The maximum current may be drawn while the respective signal line remains inactive.
- The minimum current must be drawn in order to drive the respective signal line active.
- The power supply current is a function of the operating frequency (fCPU is expressed in MHz). This dependency is illustrated in the Figure 37 below. This parameter is tested at VDDmax and at maximum CPU clock frequency with all outputs disconnected and all inputs at VIL or VIH, RSTIN pin at VIH1min: this implies I/O current is not considered. The device is doing the following:
 Fetching code from IRAM and XRAM1, accessing in read and write to both XRAM modules
 Watchdog Timer is enabled and regularly serviced
 RTC is running with main oscillator clock as reference, generating a tick interrupts every 192 clock cycles
 Four channel of XPWM are running (waves period: 2, 2.5, 3 and 4 CPU clock cycles): no output toggling
 Five General Purpose Timers are running in timer mode with prescaler equal to 8 (T2, T3, T4, T5, T6)
 ADC is in Auto Scan Continuous Conversion mode on all 16 channels of Port5
 All interrupts generated by XPWM, RTC, Timers and ADC are not serviced

10. The power supply current is a function of the operating frequency (f_{CPU} is expressed in MHz). This dependency is illustrated in the [Figure 37](#) below. This parameter is tested at V_{DDmax} and at maximum CPU clock frequency with all outputs disconnected and all inputs at V_{IL} or V_{IH} , RSTIN pin at V_{IH1min} : this implies I/O current is not considered. The device is doing the following:
- Fetching code from all sectors of IFlash, accessing in read (few fetches) and write to XRAM
 - Watchdog Timer is enabled and regularly serviced
 - RTC is running with main oscillator clock as reference, generating a tick interrupts every 192 clock cycles
 - Four channel of XPWM are running (waves period: 2, 2.5, 3 and 4 CPU clock cycles): no output toggling
 - Five General Purpose Timers are running in timer mode with prescaler equal to 8 (T2, T3, T4, T5, T6)
 - ADC is in Auto Scan Continuous Conversion mode on all 16 channels of Port5
 - All interrupts generated by XPWM, RTC, Timers and ADC are *not serviced*
11. The Idle mode supply current is a function of the operating frequency (f_{CPU} is expressed in MHz). This dependency is illustrated in the [Figure 36](#). These parameters are tested and at maximum CPU clock with all outputs disconnected and all inputs at V_{IL} or V_{IH} , RSTIN pin at V_{IH1min} .
12. This parameter is tested including leakage currents. All inputs (including pins configured as inputs) at 0 V to 0.1 V or at V_{DD} – 0.1 V to V_{DD} , $V_{AREF} = 0$ V, all outputs (including pins configured as outputs) disconnected. Besides, the Main Voltage Regulator is assumed off: in case it is not, additional 1mA shall be assumed.

Figure 36. Port2 test mode structure

Figure 37. Supply current versus the operating frequency (RUN and IDLE modes)

24.6 Flash characteristics

$$V_{DD} = 5\text{ V} \pm 10\%, V_{SS} = 0\text{ V}$$

Table 65. Flash characteristics

| Parameter | Typical | Maximum | | Unit | Notes |
|--|-------------------------|-------------------------|--------------|------|------------------------------------|
| | T _A = 25°C | T _A = 125°C | | | |
| | 0 cycles ⁽¹⁾ | 0 cycles ⁽¹⁾ | 100k cycles | | |
| Word Program (32-bit) ⁽²⁾ | 35 | 80 | 290 | μs | — |
| Double Word Program (64-bit) ⁽²⁾⁾ | 60 | 150 | 570 | μs | — |
| Bank 0 Program (256K) (Double Word Program) | 1.6 | 2.0 | 3.9 | s | — |
| Sector Erase (8K) | 0.6 0.5 | 0.9 0.8 | 1.0 0.9 | s | not preprogrammed preprogrammed |
| Sector Erase (32K) | 1.1 0.8 | 2.0 1.8 | 2.7 2.5 | s | not preprogrammed preprogrammed |
| Sector Erase (64K) | 1.7 1.3 | 3.7 3.3 | 5.1 4.7 | s | not preprogrammed preprogrammed |
| Bank 0 Erase (256K) ⁽³⁾ | 5.6 4.0 | 13.6 11.9 | 19.2 17.5 | s | not preprogrammed preprogrammed |
| Recovery from Power-Down (t _{PD}) | — | 40 | 40 | μs | ⁽⁴⁾ |
| Program Suspend Latency ⁽⁴⁾ | — | 10 | 10 | μs | |
| Erase Suspend Latency ⁽⁴⁾ | — | 30 | 30 | μs | |
| Erase Suspend Request Rate ⁽⁴⁾ | 20 | 20 | 20 | ms | Min delay between 2 requests |
| Set Protection ⁽⁴⁾ | 40 | 90 | 300 | μs | |

1. The figures are given after about 100 cycles due to testing routines (0 cycles at the final customer).
2. Word and Double Word Programming times are provided as average values derived from a full sector programming time: absolute value of a Word or Double Word Programming time could be longer than the average value.
3. Bank Erase is obtained through a multiple Sector Erase operation (setting bits related to all sectors of the Bank). As ST10F272 implements only one bank, the Bank Erase operation is equivalent to Module and Chip Erase operations.
4. Not 100% tested, guaranteed by Design Characterization.

Table 66. Flash data retention characteristics

| Number of program / erase cycles (-40°C ≤ T _A ≤ 125°C) | Data retention time (average ambient temperature 60°C) | |
|--|---|---|
| | 256Kbyte (code store) | 64Kbyte (EEPROM emulation) ⁽¹⁾ |
| 0 - 100 | > 20 years | > 20 years |
| 1,000 | - | > 20 years |
| 10,000 | - | 10 years |
| 100,000 | - | 1 year |

1. Two 64Kbyte Flash Sectors may be typically used to emulate up to 4, 8 or 16Kbyte of EEPROM. Therefore, in case of an emulation of a 16Kbyte EEPROM, 100,000 Flash Program / Erase cycles are equivalent to 800,000 EEPROM Program/Erase cycles. For an efficient use of the EEPROM Emulation please refer to dedicated Application Note document ([AN2061 - "EEPROM Emulation with ST10F2xx"](#)). Contact your local field service, local sales person or STMicroelectronics representative to get copy of such a guideline document.

24.7 A/D converter characteristics

$$V_{DD} = 5V \pm 10\%, V_{SS} = 0V, T_A = -40 \text{ to } +125^\circ\text{C}, 4.5V \leq V_{AREF} \leq V_{DD}, \\ V_{SS} \leq V_{AGND} \leq V_{SS} + 0.2V$$

Table 67. A/D converter characteristics

| Parameter | Symbol | Limit Values | | Unit | Test Condition |
|--|----------------------|----------------------|-----------------------|----------|--|
| | | min. | max. | | |
| Analog Reference voltage 1) | V _{AREF} SR | 4.5 | V _{DD} | V | |
| Analog Ground voltage | V _{AGND} SR | V _{SS} | V _{SS} + 0.2 | V | |
| Analog Input voltage 2) | V _{AIN} SR | V _{AGND} | V _{AREF} | V | |
| Reference supply current | I _{AREF} CC | – | 5 1 | mA μA | Running mode ³⁾ Power Down mode |
| Sample time | t _s CC | 1 | – | μs | ⁴⁾ |
| Conversion time | t _c CC | 3 | – | μs | ⁵⁾ |
| Differential Non Linearity ⁶⁾ | DNL CC | –1 | +1 | LSB | No overload |
| Integral Non Linearity ⁶⁾ | INL CC | –1.5 | +1.5 | LSB | No overload |
| Offset Error ⁶⁾ | OFS CC | –1.5 | +1.5 | LSB | No overload |
| Total unadjusted error ⁶⁾ | TUE CC | –2.0 –5.0 –7.0 | +2.0 +5.0 +7.0 | LSB | Port5 Port1 - No overload ³⁾ Port1 - Overload ³⁾ |
| Coupling Factor between inputs 3) 7) | K CC | – | 10 ^{–6} | – | On both Port5 and Port1 |
| Input Pin Capacitance ^{3) 8)} | C _{P1} CC | – | 3 | pF | |
| | C _{P2} CC | – | 4 6 | pF | Port5 Port1 |
| Sampling Capacitance ^{3) 8)} | C _S CC | – | 3.5 | pF | |

Table 67. A/D converter characteristics

| Parameter | Symbol | Limit Values | | Unit | Test Condition |
|---|--------------------|--------------|------|------|----------------|
| | | min. | max. | | |
| Analog Switch Resistance ^{3) 8)} | R _{SW} CC | — | 600 | W | Port5 |
| | R _{AD} CC | — | 1300 | W | Port1 |

- V_{AREF} can be tied to ground when A/D Converter is not in use: an extra consumption (around 200µA) on main V_{DD} is added due to internal analogue circuitry not completely turned off: so, it is suggested to maintain the V_{AREF} at V_{DD} level even when not in use, and eventually switch off the A/D Converter circuitry setting bit ADOFF in ADCON register.
- V_{AIN} may exceed V_{AGND} or V_{AREF} up to the absolute maximum ratings. However, the conversion result in these cases will be 0x000_H or 0x3FF_H, respectively.
- Not 100% tested, guaranteed by design characterization.
- During the sample time the input capacitance C_{AIN} can be charged/discharged by the external source. The internal resistance of the analog source must allow the capacitance to reach its final voltage level within t_S. After the end of the sample time t_S, changes of the analog input voltage have no effect on the conversion result.
Values for the sample clock t_S depends on programming and can be taken from [Table 68: A/D converter programming](#).
- This parameter includes the sample time t_S, the time for determining the digital result and the time to load the result register with the conversion result. Values for the conversion clock t_{CC} depend on programming and can be taken from next [Table 68](#).
- DNL, INL, OFS and TUE are tested at V_{AREF} = 5.0 V, V_{AGND} = 0V, V_{DD} = 5.0 V. It is guaranteed by design characterization for all other voltages within the defined voltage range.
'LSB' has a value of V_{AREF}/1024.
For Port5 channels, the specified TUE (± 2LSB) is guaranteed also with an overload condition (see I_{OY} specification) occurring on maximum 2 not selected analog input pins of Port5 and the absolute sum of input overload currents on all Port5 analog input pins does not exceed 10 mA.
For Port1 channels, the specified TUE is guaranteed when no overload condition is applied to Port1 pins: when an overload condition occurs on maximum 2 not selected analog input pins of Port1 and the input positive overload current on all analog input pins does not exceed 10 mA (either dynamic or static injection), the specified TUE is degraded (± 7LSB). To get the same accuracy, the negative injection current on Port1 pins shall not exceed -1mA in case of both dynamic and static injection.
- The coupling factor is measured on a channel while an overload condition occurs on the adjacent not selected channels with the overload current within the different specified ranges (for both positive and negative injection current).
- Refer to scheme reported in [Figure 39](#).

24.7.1 Conversion timing control

When a conversion is started, first the capacitances of the converter are loaded via the respective analog input pin to the current analog input voltage. The time to load the capacitances is referred to as sample time. Next the sampled voltage is converted to a digital value several successive steps, which correspond to the 10-bit resolution of the ADC. During these steps the internal capacitances are repeatedly charged and discharged via the V_{AREF} pin.

The current that has to be drawn from the sources for sampling and changing charges depends on the time that each respective step takes, because the capacitors must reach their final voltage level within the given time, at least with a certain approximation. The maximum current, however, that a source can deliver, depends on its internal resistance.

The time that the two different actions during conversion take (sampling, and converting) can be programmed within a certain range in the ST10F272 relative to the CPU clock. The absolute time that is consumed by the different conversion steps therefore is independent from the general speed of the controller. This allows adjusting the A/D converter of the ST10F272 to the properties of the system:

Fast conversion can be achieved by programming the respective times to their absolute possible minimum. This is preferable for scanning high frequency signals. The internal resistance of analog source and analog supply must be sufficiently low, however.

High internal resistance can be achieved by programming the respective times to a higher value, or the possible maximum. This is preferable when using analog sources and supply with a high internal resistance in order to keep the current as low as possible. The conversion rate in this case may be considerably lower, however.

The conversion times are programmed via the upper four bits of register ADCON. Bit fields ADCTC and ADSTC are used to define the basic conversion time and in particular the partition between sample phase and comparison phases. [Table 68](#) lists the possible combinations. The timings refer to the unit TCL, where $f_{CPU} = 1/2TCL$. A complete conversion time includes the conversion itself, the sample time and the time required to transfer the digital value to the result register.

Table 68. A/D converter programming

| ADCTC | ADSTC | Sample | Comparison | Extra | Total conversion |
|-------|-------|------------|------------|-----------|------------------|
| 00 | 00 | TCL * 120 | TCL * 240 | TCL * 28 | TCL * 388 |
| 00 | 01 | TCL * 140 | TCL * 280 | TCL * 16 | TCL * 436 |
| 00 | 10 | TCL * 200 | TCL * 280 | TCL * 52 | TCL * 532 |
| 00 | 11 | TCL * 400 | TCL * 280 | TCL * 44 | TCL * 724 |
| 11 | 00 | TCL * 240 | TCL * 480 | TCL * 52 | TCL * 772 |
| 11 | 01 | TCL * 280 | TCL * 560 | TCL * 28 | TCL * 868 |
| 11 | 10 | TCL * 400 | TCL * 560 | TCL * 100 | TCL * 1060 |
| 11 | 11 | TCL * 800 | TCL * 560 | TCL * 52 | TCL * 1444 |
| 10 | 00 | TCL * 480 | TCL * 960 | TCL * 100 | TCL * 1540 |
| 10 | 01 | TCL * 560 | TCL * 1120 | TCL * 52 | TCL * 1732 |
| 10 | 10 | TCL * 800 | TCL * 1120 | TCL * 196 | TCL * 2116 |
| 10 | 11 | TCL * 1600 | TCL * 1120 | TCL * 164 | TCL * 2884 |

Note: The total conversion time is compatible with the formula valid for ST10F269, while the meaning of the bit fields ADCTC and ADSTC is no longer compatible: the minimum conversion time is 388 TCL, which at 40MHz CPU frequency corresponds to 4.85μs (see ST10F269).

24.7.2 A/D conversion accuracy

The A/D Converter compares the analog voltage sampled on the selected analog input channel to its analog reference voltage (V_{AREF}) and converts it into 10-bit digital data. The absolute accuracy of the A/D conversion is the deviation between the input analog value and the output digital value. It includes the following errors:

- Offset error (OFS)
- Gain Error (GE)
- Quantization error
- Non-Linearity error (Differential and Integral)

These four error quantities are explained below using [Figure 38](#).

Offset error

Offset error is the deviation between actual and ideal A/D conversion characteristics when the digital output value changes from the minimum (zero voltage) 00 to 01 ([Figure 38](#), see OFS).

Gain error

Gain error is the deviation between the actual and ideal A/D conversion characteristics when the digital output value changes from the 3FE to the maximum 3FF, once offset error is subtracted. Gain error combined with offset error represents the so-called full-scale error ([Figure 38](#), OFS + GE).

Quantization error

Quantization error is the intrinsic error of the A/D converter and is expressed as 1/2 LSB.

Non-linearity error

Non-Linearity error is the deviation between actual and the best-fitting A/D conversion characteristics (see [Figure 38](#)):

- Differential Non-Linearity error is the actual step dimension versus the ideal one ($1 \text{ LSB}_{\text{IDEAL}}$).
- Integral Non-Linearity error is the distance between the center of the actual step and the center of the bisector line, in the actual characteristics. Note that for Integral Non-Linearity error, the effect of offset, gain and quantization errors is not included.

Note: Bisector characteristic is obtained drawing a line from 1/2 LSB before the first step of the real characteristic, and 1/2 LSB after the last step again of the real characteristic.

24.7.3 Total unadjusted error

The Total Unadjusted Error specifies the maximum deviation from the ideal characteristic: the number provided in the Data Sheet represents the maximum error with respect to the entire characteristic. It is a combination of the Offset, Gain and Integral Linearity errors. The different errors may compensate each other depending on the relative sign of the Offset and Gain errors. Refer to [Figure 38](#), see TUE.

Figure 38. A/D conversion characteristic

24.7.4 Analog reference pins

The accuracy of the A/D converter depends on how accurate is its analog reference: a noise in the reference results in at least that much error in a conversion. A low pass filter on the A/D converter reference source (supplied through pins V_{AREF} and V_{AGND}), is recommended in order to clean the signal, minimizing the noise. A simple capacitive bypassing may be sufficient in most of the cases; in presence of high RF noise energy, inductors or ferrite beads may be necessary.

In this architecture, V_{AREF} and V_{AGND} pins represents also the power supply of the analog circuitry of the A/D converter: there is an effective DC current requirement from the reference voltage by the internal resistor string in the R-C DAC array and by the rest of the analog circuitry.

An external resistance on V_{AREF} could introduce error under certain conditions: for this reasons, series resistance are not advisable, and more in general any series devices in the filter network should be designed to minimize the DC resistance.

Analog Input pins

To improve the accuracy of the A/D converter, it is definitively necessary that analog input pins have low AC impedance. Placing a capacitor with good high frequency characteristics at the input pin of the device, can be effective: the capacitor should be as large as possible, ideally infinite. This capacitor contributes to attenuating the noise present on the input pin;

besides, it sources charge during the sampling phase, when the analog signal source is a high-impedance source.

A real filter, can typically be obtained by using a series resistance with a capacitor on the input pin (simple RC Filter). The RC filtering may be limited according to the value of source impedance of the transducer or circuit supplying the analog signal to be measured. The filter at the input pins must be designed taking into account the dynamic characteristics of the input signal (bandwidth).

Figure 39. A/D converter input pins scheme

Input Leakage and external circuit

The series resistor utilized to limit the current to a pin (see R_L in [Figure 39](#)), in combination with a large source impedance can lead to a degradation of A/D converter accuracy when input leakage is present.

Data about maximum input leakage current at each pin are provided in the Data Sheet (see [Section 24: Electrical characteristics](#)). Input leakage is greatest at high operating temperatures, and in general it decreases by one half for each 10°C decrease in temperature.

Considering that, for a 10-bit A/D converter one count is about 5mV (assuming $V_{AREF} = 5V$), an input leakage of 100nA acting through an $R_L = 50k\Omega$ of external resistance leads to an error of exactly one count (5mV); if the resistance were 100k Ω the error would become two counts.

Eventual additional leakage due to external clamping diodes must also be taken into account in computing the total leakage affecting the A/D converter measurements. Another contribution to the total leakage is represented by the charge sharing effects with the sampling capacitance: being C_S substantially a switched capacitance, with a frequency equal to the conversion rate of a single channel (maximum when fixed channel continuous conversion mode is selected), it can be seen as a resistive path to ground. For instance, assuming a conversion rate of 250kHz, with C_S equal to 4pF, a resistance of 1M Ω is obtained ($R_{EQ} = 1 / f_C C_S$, where f_C represents the conversion rate at the considered channel). To minimize the error induced by the voltage partitioning between this resistance

(sampled voltage on C_S) and the sum of $R_S + R_F + R_L + R_{SW} + R_{AD}$, the external circuit must be designed to respect the following relation:

Equation 1

$$V_A \cdot \frac{R_S + R_F + R_L + R_{SW} + R_{AD}}{R_{EQ}} < \frac{1}{2} \text{ LSB}$$

The formula above provides a constraints for external network design, in particular on resistive path.

A second aspect involving the capacitance network shall be considered. Assuming the three capacitances C_F , C_{P1} and C_{P2} initially charged at the source voltage V_A (refer to the equivalent circuit reported in [Figure 39](#)), when the sampling phase is started (A/D switch close), a charge sharing phenomena is installed.

Figure 40. Charge sharing timing diagram during sampling phase

In particular two different transient periods can be distinguished (see [Figure 40](#)):

- A first and quick charge transfer from the internal capacitance C_{P1} and C_{P2} to the sampling capacitance C_S occurs (C_S is supposed initially completely discharged): considering a worst case (since the time constant in reality would be faster) in which C_{P2} is reported in parallel to C_{P1} (call $C_P = C_{P1} + C_{P2}$), the two capacitance C_P and C_S are in series, and the time constant is:

Equation 2

$$\tau_1 = (R_{SW} + R_{AD}) \cdot \frac{C_P \cdot C_S}{C_P + C_S}$$

- This relation can again be simplified considering only C_S as an additional worst condition. In reality, the transient is faster, but the A/D Converter circuitry has been designed to be robust also in the very worst case: the sampling time T_S is always much longer than the internal time constant:

Equation 3

$$\tau_1 < (R_{SW} + R_{AD}) \cdot C_S < T_S$$

The charge of C_{P1} and C_{P2} is redistributed also on C_S , determining a new value of the voltage V_{A1} on the capacitance according to the following equation:

Equation 4

$$V_{A1} \cdot (C_S + C_{P1} + C_{P2}) = V_A \cdot (C_{P1} + C_{P2})$$

- A second charge transfer involves also C_F (that is typically bigger than the on-chip capacitance) through the resistance R_L : again considering the worst case in which C_{P2} and C_S were in parallel to C_{P1} (since the time constant in reality would be faster), the time constant is:

Equation 5

$$\tau_2 < R_L \cdot (C_S + C_{P1} + C_{P2})$$

In this case, the time constant depends on the external circuit: in particular imposing that the transient is completed well before the end of sampling time T_S , a constraints on R_L sizing is obtained:

Equation 6

$$10 \cdot \tau_2 = 10 \cdot R_L \cdot (C_S + C_{P1} + C_{P2}) \leq T_S$$

Of course, R_L shall be sized also according to the current limitation constraints, in combination with R_S (source impedance) and R_F (filter resistance). Being C_F definitively bigger than C_{P1} , C_{P2} and C_S , then the final voltage V_{A2} (at the end of the charge transfer transient) will be much higher than V_{A1} . The following equation must be respected (charge balance assuming now C_S already charged at V_{A1}):

Equation 7

$$V_{A2} (C_S + C_{P1} + C_{P2} + C_F) = V_A \cdot C_F + V_{A1} (C_{P1} + C_{P2} + C_S)$$

The two transients above are not influenced by the voltage source that, due to the presence of the $R_F C_F$ filter, is not able to provide the extra charge to compensate the voltage drop on C_S with respect to the ideal source V_A ; the time constant $R_F C_F$ of the filter is very high with respect to the sampling time (T_S). The filter is typically designed to act as anti-aliasing (see [Figure 41](#)).

Calling f_0 the bandwidth of the source signal (and as a consequence the cut-off frequency of the anti-aliasing filter, f_F), according to Nyquist theorem the conversion rate f_C must be at least $2f_0$; it means that the constant time of the filter is greater than or at least equal to twice the conversion period (T_C). Again the conversion period T_C is longer than the sampling time T_S , which is just a portion of it, even when fixed channel continuous conversion mode is selected (fastest conversion rate at a specific channel): in conclusion it is evident that the time constant of the filter $R_F C_F$ is definitively much higher than the sampling time T_S , so the charge level on C_S cannot be modified by the analog signal source during the time in which the sampling switch is closed.

Figure 41. Anti-aliasing filter and conversion rate

The considerations above lead to impose new constraints to the external circuit, to reduce the accuracy error due to the voltage drop on C_S ; from the two charge balance equations above, it is simple to derive the following relation between the ideal and real sampled voltage on C_S :

Equation 8

$$\frac{V_A}{V_{A2}} = \frac{C_{P1} + C_{P2} + C_F}{C_{P1} + C_{P2} + C_F + C_S}$$

From this formula, in the worst case (when V_A is maximum, that is for instance 5V), assuming to accept a maximum error of half a count ($\sim 2.44\text{mV}$), it is immediately evident a constraints on C_F value:

Equation 9

$$C_F > 2048 C_S$$

In the next section an example of how to design the external network is provided, assuming some reasonable values for the internal parameters and making hypothesis on the characteristics of the analog signal to be sampled.

Example of external network sizing

The following hypothesis are formulated in order to proceed in designing the external network on A/D Converter input pins:

- Analog Signal Source Bandwidth (f_0):10kHz
- conversion Rate (f_C):25kHz
- Sampling Time (T_S):1 μ s
- Pin Input Capacitance (C_{P1}):5pF
- Pin Input Routing Capacitance (C_{P2}):1pF
- Sampling Capacitance (C_S):4pF
- Maximum Input Current Injection (I_{INJ}):3mA
- Maximum Analog Source Voltage (V_{AM}):12V
- Analog Source Impedance (R_S):100 Ω
- Channel Switch Resistance (R_{SW}):500 Ω
- Sampling Switch Resistance (R_{AD}):200 Ω

1. Supposing to design the filter with the pole exactly at the maximum frequency of the signal, the time constant of the filter is:

Equation 10

$$R_C C_F = \frac{1}{2\pi f_0} = 15.9\mu s$$

2. Using the relation between C_F and C_S and taking some margin (4000 instead of 2048), it is possible to define C_F :

Equation 11

$$C_F = 4000 C_S = 16nF$$

3. As a consequence of step 1 and 2, RC can be chosen:

Equation 12

$$R_F = \frac{1}{2\pi f_0 C_F} = 995\Omega \cong 1k\Omega$$

4. Considering the current injection limitation and supposing that the source can go up to 12V, the total series resistance can be defined as:

Equation 13

$$R_S + R_F + R_L = \frac{V_{AM}}{I_{INJ}} = 4k\Omega$$

from which is now simple to define the value of R_L :

Equation 14

$$R_L = \frac{V_{AM}}{I_{INJ}} - R_F - R_S = 2.9k\Omega$$

5. Now the three element of the external circuit R_F , C_F and R_L are defined. Some conditions discussed in the previous paragraphs have been used to size the component, the other must now be verified. The relation which allow to minimize the accuracy error introduced by the switched capacitance equivalent resistance is in this case:

Equation 15

$$R_{EQ} = \frac{1}{f_C C_S} = 10M\Omega$$

So the error due to the voltage partitioning between the real resistive path and C_S is less than half a count (considering the worst case when $V_A = 5V$):

Equation 16

$$V_A \cdot \frac{R_S + R_F + R_L + R_{SW} + R_{AD}}{R_{EQ}} = 2.35mV < \frac{1}{2}LSB$$

The other conditions to be verified is the time constants of the transients are really and significantly shorter than the sampling period duration T_S :

Equation 17

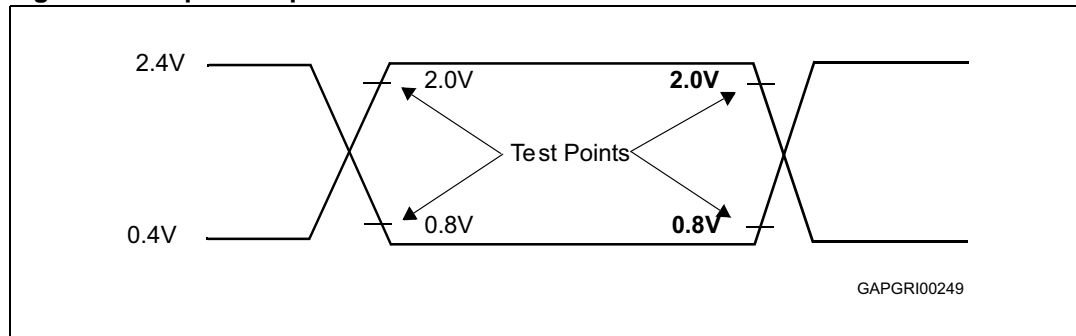

$$\begin{aligned} \tau_1 &= (R_{SW} + R_{AD}) \cdot C_S = 2.8ns \ll T_S = 1\mu s \\ 10 \tau_2 &= 10 R_L (C_S + C_{P1} + C_{P2}) = 290ns < T_S = 1\mu s \end{aligned}$$

For complete set of parameters characterizing the ST10F272 A/D Converter equivalent circuit, refer to [Section 24.7: A/D converter characteristics](#).

24.8 AC characteristics

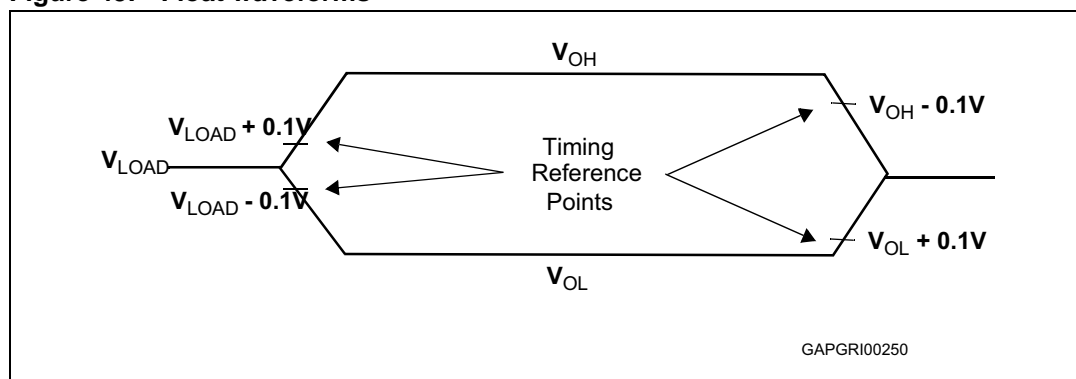

24.8.1 Test waveforms

Figure 42. Input / output waveforms

Note: AC inputs during testing are driven at 2.4V for a logic '1' and 0.4V for a logic '0'.
Timing measurements are made at V_{IH} min. for a logic '1' and V_{IL} max for a logic '0'.

Figure 43. Float waveforms

Note: For timing purposes a port pin is no longer floating when V_{LOAD} changes of $\pm 100\text{mV}$.
It begins to float when a 100mV change from the loaded V_{OH}/V_{OL} level occurs ($I_{OH}/I_{OL} = 20\text{mA}$).

24.8.2 Definition of internal timing

The internal operation of the ST10F272 is controlled by the internal CPU clock f_{CPU} . Both edges of the CPU clock can trigger internal (for example pipeline) or external (for example bus cycles) operations.

The specification of the external timing (AC Characteristics) therefore depends on the time between two consecutive edges of the CPU clock, called "TCL".

The CPU clock signal can be generated by different mechanisms. The duration of TCL and its variation (and also the derived external timing) depends on the mechanism used to generate f_{CPU} .

This influence must be regarded when calculating the timings for the ST10F272.

The example for PLL operation shown in [Figure 44](#) refers to a PLL factor of 4.

The mechanism used to generate the CPU clock is selected during reset by the logic levels on pins P0.15-13 (P0H.7-5).

Figure 44. Generation mechanisms for the CPU clock

24.8.3 Clock generation modes

[Table 69](#) associates the combinations of these three bits with the respective clock generation mode.

Table 69. On-chip clock generator selections

| P0.15-13 (P0H.7-5) | | | CPU Frequency $f_{CPU} = f_{XTAL} \times F$ | External Clock Input Range ^{1) 3)} | Notes |
|-----------------------|---|---|--|--|--|
| 1 | 1 | 1 | $F_{XTAL} \times 4$ | 4 to 8MHz | Default configuration |
| 1 | 1 | 0 | $F_{XTAL} \times 3$ | 5.3 to 8MHz | |
| 1 | 0 | 1 | $F_{XTAL} \times 8$ | 4 to 8MHz | |
| 1 | 0 | 0 | $F_{XTAL} \times 5$ | 6.4 to 8MHz | |
| 0 | 1 | 1 | $F_{XTAL} \times 1$ | 1 to 64MHz | Direct Drive (oscillator bypassed) ²⁾ |
| 0 | 1 | 0 | $F_{XTAL} \times 10$ | 4 to 6.4MHz | |
| 0 | 0 | 1 | $F_{XTAL} / 2$ | 4 to 8MHz | CPU clock via prescaler ³⁾ |
| 0 | 0 | 0 | $F_{XTAL} \times 16$ | 4MHz | |

1. The external clock input range refers to a CPU clock range of 1...64 MHz. Besides, the PLL usage is limited to 4-8MHz. All configurations need a crystal (or ceramic resonator) to generate the CPU clock through the internal oscillator amplifier (apart from Direct Drive): vice versa, the clock can be forced through an external clock source only in Direct Drive mode (on-chip oscillator amplifier disabled, so no crystal or resonator can be used).
2. The maximum depends on the duty cycle of the external clock signal: when 64MHz is used, 50% duty cycle shall be granted (low phase = high phase = 7.8ns); when 32MHz is selected a 25% duty cycle can be

accepted (minimum phase, high or low, again equal to 7.8ns).

3. The limits on input frequency are 4-8MHz since the usage of the internal oscillator amplifier is required. Also when the PLL is not used and the CPU clock corresponds to $F_{XTAL}/2$, an external crystal or resonator shall be used: it is not possible to force any clock through an external clock source.

24.8.4 Prescaler operation

When pins P0.15-13 (P0H.7-5) equal '001' during reset, the CPU clock is derived from the internal oscillator (input clock signal) by a 2:1 prescaler.

The frequency of f_{CPU} is half the frequency of f_{XTAL} and the high and low time of f_{CPU} (i.e. the duration of an individual TCL) is defined by the period of the input clock f_{XTAL} .

The timings listed in the AC Characteristics that refer to TCL therefore can be calculated using the period of f_{XTAL} for any TCL.

Note that if the bit OWDDIS in SYSCON register is cleared, the PLL runs on its free-running frequency and delivers the clock signal for the Oscillator Watchdog. If bit OWDDIS is set, then the PLL is switched off.

24.8.5 Direct drive

When pins P0.15-13 (P0H.7-5) equal '011' during reset the on-chip phase locked loop is disabled, the on-chip oscillator amplifier is bypassed and the CPU clock is directly driven by the input clock signal on XTAL1 pin.

The frequency of CPU clock (f_{CPU}) directly follows the frequency of f_{XTAL} so the high and low time of f_{CPU} (i.e. the duration of an individual TCL) is defined by the duty cycle of the input clock f_{XTAL} .

Therefore, the timings given in this chapter refer to the minimum TCL. This minimum value can be calculated by the following formula:

Equation 18

$$\text{TCL}_{\min} = 1/f_{\text{XTAL}} \times \text{DC}_{\min}$$

DC = duty cycle

For two consecutive TCLs, the deviation caused by the duty cycle of f_{XTAL} is compensated, so the duration of 2TCL is always $1/f_{\text{XTAL}}$.

The minimum value TCL_{\min} has to be used only once for timings that require an odd number of TCLs (1,3,...). Timings that require an even number of TCLs (2,4,...) may use the formula:

Equation 19

$$2\text{TCL} = 1/f_{\text{XTAL}}$$

The address float timings in Multiplexed bus mode (t_{11} and t_{45}) use the maximum duration of TCL ($\text{TCL}_{\max} = 1/f_{\text{XTAL}} \times \text{DC}_{\max}$) instead of TCL_{\min} .

Similarly to what happen for Prescaler Operation, if the bit OWDDIS in SYSCON register is cleared, the PLL runs on its free-running frequency and delivers the clock signal for the Oscillator Watchdog. If bit OWDDIS is set, then the PLL is switched off.

24.8.6 Oscillator watchdog (OWD)

An on-chip watchdog oscillator is implemented in the ST10F272. This feature is used for safety operation with external crystal oscillator (available only when using direct drive mode with or without prescaler, so the PLL is not used to generate the CPU clock multiplying the frequency of the external crystal oscillator). This watchdog oscillator operates as following.

The reset default configuration enables the watchdog oscillator. It can be disabled by setting the OWDDIS (bit 4) of SYSCON register.

When the OWD is enabled, the PLL runs at its free-running frequency, and it increments the watchdog counter. On each transition of external clock, the watchdog counter is cleared. If an external clock failure occurs, then the watchdog counter overflows (after 16 PLL clock cycles).

The CPU clock signal will be switched to the PLL free-running clock signal, and the oscillator watchdog Interrupt Request is flagged. The CPU clock will not switch back to the external clock even if a valid external clock exists on XTAL1 pin. Only a hardware reset (or bidirectional Software / Watchdog reset) can switch the CPU clock source back to direct clock input.

When the OWD is disabled, the CPU clock is always the external oscillator clock (in Direct Drive or Prescaler Operation) and the PLL is switched off to decrease consumption supply current.

24.8.7 Phase Locked Loop (PLL)

For all other combinations of pins P0.15-13 (P0H.7-5) during reset the on-chip phase locked loop is enabled and it provides the CPU clock (see [Table 69](#)). The PLL multiplies the input frequency by the factor F which is selected via the combination of pins P0.15-13 ($f_{\text{CPU}} = f_{\text{XTAL}} \times F$). With every F'th transition of f_{XTAL} the PLL circuit synchronizes the CPU clock to the input clock. This synchronization is done smoothly, so the CPU clock frequency does not change abruptly.

Due to this adaptation to the input clock the frequency of f_{CPU} is constantly adjusted so it is locked to f_{XTAL} . The slight variation causes a jitter of f_{CPU} which also effects the duration of individual TCLs.

The timings listed in the AC Characteristics that refer to TCLs therefore must be calculated using the minimum TCL that is possible under the respective circumstances.

The real minimum value for TCL depends on the jitter of the PLL. The PLL tunes f_{CPU} to keep it locked on f_{XTAL} . The relative deviation of TCL is the maximum when it is referred to one TCL period.

This is especially important for bus cycles using wait states and e.g. for the operation of timers, serial interfaces, etc. For all slower operations and longer periods (e.g. pulse train generation or measurement, lower Baud rates, etc.) the deviation caused by the PLL jitter is negligible. Refer to next [Section 24.8.9: PLL Jitter](#) for more details.

24.8.8 Voltage Controlled Oscillator

The ST10F272 implements a PLL which combines different levels of frequency dividers with a Voltage Controlled Oscillator (VCO) working as frequency multiplier. In [Table 70](#), a detailed summary of the internal settings and VCO frequency is reported.

Table 70. Internal PLL divider mechanism

| P0.15-13 (P0H.7-5) | XTAL Frequency | Input Prescaler | PLL | | Output Prescaler | CPU Frequency $f_{CPU} = f_{XTAL} \times F$ |
|-----------------------|------------------------------|--------------------|--------------|-----------|---------------------|--|
| | | | Multiply by | Divide by | | |
| 1 1 1 | 4 to 8MHz | $F_{XTAL} / 4$ | 64 | 4 | — | $F_{XTAL} \times 4$ |
| 1 1 0 | 5.3 to 10.6MHz ¹⁾ | $F_{XTAL} / 4$ | 48 | 4 | — | $F_{XTAL} \times 3$ |
| 1 0 1 | 4 to 8MHz | $F_{XTAL} / 4$ | 64 | 2 | — | $F_{XTAL} \times 8$ |
| 1 0 0 | 6.4 to 12MHz ¹⁾ | $F_{XTAL} / 4$ | 40 | 2 | — | $F_{XTAL} \times 5$ |
| 0 1 1 | 1 to 64MHz | — | PLL bypassed | | — | $F_{XTAL} \times 1$ |
| 0 1 0 | 4 to 6.4MHz | $F_{XTAL} / 2$ | 40 | 2 | — | $F_{XTAL} \times 10$ |
| 0 0 1 | 4 to 12MHz ¹⁾ | — | PLL bypassed | | $F_{PLL} / 2$ | $F_{XTAL} / 2$ |
| 0 0 0 | 4MHz | $F_{XTAL} / 2$ | 64 | 2 | — | $F_{XTAL} \times 16$ |

The PLL input frequency range is limited to 1 to 3.5MHz, while the VCO oscillation range is 64 to 128MHz. The CPU clock frequency range when PLL is used is 16 to 64MHz.

Example 1

- $F_{XTAL} = 4\text{MHz}$
- P0(15:13) = '110' (Multiplication by 3)
- PLL Input Frequency = 1MHz
- VCO frequency = 48MHz
- PLL Output Frequency = 12MHz
(VCO frequency divided by 4)
- $F_{CPU} = 12\text{MHz}$ (no effect of Output Prescaler)

Example 2

- $F_{XTAL} = 8\text{MHz}$
- P0(15:13) = '100' (Multiplication by 5)
- PLL Input Frequency = 2MHz
- VCO frequency = 80MHz
- PLL Output Frequency = 40MHz (VCO frequency divided by 2)
- $F_{CPU} = 40\text{MHz}$ (no effect of Output Prescaler)

24.8.9 PLL Jitter

The following terminology is hereafter defined:

- **Self referred single period jitter**
Also called "Period Jitter", it can be defined as the difference of the T_{max} and T_{min} , where T_{max} is maximum time period of the PLL output clock and T_{min} is the minimum time period of the PLL output clock.
- **Self referred long term jitter**
Also called "N period jitter", it can be defined as the difference of T_{max} and T_{min} , where T_{max} is the maximum time difference between N+1 clock rising edges and T_{min} is the minimum time difference between N+1 clock rising edges. Here N should be kept

sufficiently large to have the long term jitter. For $N=1$, this becomes the single period jitter.

Jitter at the PLL output can be due to the following reasons:

- Jitter in the input clock
- Noise in the PLL loop.

Jitter in the input clock

PLL acts like a low pass filter for any jitter in the input clock. Input Clock jitter with the frequencies within the PLL loop bandwidth is passed to the PLL output and higher frequency jitter (frequency > PLL bandwidth) is attenuated @20dB/decade.

Noise in the PLL loop

This contribution again can be caused by the following sources:

- Device noise of the circuit in the PLL
- Noise in supply and substrate.

Device noise of the circuit in the PLL

The long term jitter is inversely proportional to the bandwidth of the PLL: the wider is the loop bandwidth, the lower is the jitter due to noise in the loop. Besides, the long term jitter is practically independent on the multiplication factor.

The most noise sensitive circuit in the PLL circuit is definitively the VCO (Voltage Controlled Oscillator). There are two main sources of noise: thermal (random noise, frequency independent so practically white noise) and flicker (low frequency noise, $1/f$). For the frequency characteristics of the VCO circuitry, the effect of the thermal noise results in a $1/f^2$ region in the output noise spectrum, while the flicker noise in a $1/f^3$. Assuming a noiseless PLL input and supposing that the VCO is dominated by its $1/f^2$ noise, the R.M.S. value of the accumulated jitter is *proportional to the square root of N*, where N is the number of clock periods within the considered time interval.

On the contrary, assuming again a noiseless PLL input and supposing that the VCO is dominated by its $1/f^3$ noise, the R.M.S. value of the accumulated jitter is *proportional to N*, where N is the number of clock periods within the considered time interval.

The jitter in the PLL loop can be modeled as dominated by the $1/f^2$ noise for N smaller than a certain value depending on the PLL output frequency and on the bandwidth characteristics of loop. Above this first value, the jitter becomes dominated by the $1/f^3$ noise component. Lastly, for N greater than a second value of N, a saturation effect is evident, so the jitter does not grow anymore when considering a longer time interval (jitter stable increasing the number of clock periods N). The PLL loop acts as a high pass filter for any noise in the loop, with cutoff frequency equal to the bandwidth of the PLL. The saturation value corresponds to what has been called self referred long term jitter of the PLL. In [Figure 45](#) the maximum jitter trend versus the number of clock periods N (for some typical CPU frequencies) is reported: the curves represent the very worst case, computed taking into account all corners of temperature, power supply and process variations: the real jitter is always measured well below the given worst case values.

Noise in supply and substrate

Digital supply noise adds deterministic components to the PLL output jitter, independent on multiplication factor. Its effects is strongly reduced thanks to particular care used in the physical implementation and integration of the PLL module inside the device. Anyhow, the

contribution of the digital noise to the global jitter is widely taken into account in the curves provided in [Figure 45](#).

Figure 45. ST10F272 PLL jitter

24.8.10 PLL lock / unlock

During normal operation, if the PLL gets unlocked for any reason, an interrupt request to the CPU is generated, and the reference clock (oscillator) is automatically disconnected from the PLL input: in this way, the PLL goes into free-running mode, providing the system with a backup clock signal (free running frequency F_{free}). This feature allows to recover from a crystal failure occurrence without risking to go in an undefined configuration: the system is provided with a clock allowing the execution of the PLL unlock interrupt routine in a safe mode.

The path between reference clock and PLL input can be restored only by a hardware reset, or by a bidirectional software or watchdog reset event that forces the \overline{RSTIN} pin low.

Note: *The external RC circuit on \overline{RSTIN} pin shall be properly sized in order to extend the duration of the low pulse to grant the PLL gets locked before the level at \overline{RSTIN} pin is recognized high: bidirectional reset internally drives \overline{RSTIN} pin low for just 1024 TCL (definitively not sufficient to get the PLL locked starting from free-running mode).*

Table 71. PLL characteristics ($V_{DD} = 5V \pm 10\%$, $V_{SS} = 0V$, $T_A = -40$ to $+125^\circ C$)

| Symbol | Parameter | Conditions | Value | | Unit |
|------------|--|--|------------|--------------|---------|
| | | | min. | max. | |
| T_{PSUP} | PLL Start-up time ¹⁾ | Stable V_{DD} and reference clock | – | 300 | μs |
| T_{LOCK} | PLL Lock-in time | Stable V_{DD} and reference clock, starting from free-running mode | – | 250 | μs |
| T_{JIT} | Single Period Jitter ¹⁾ (cycle to cycle = 2 TCL) | 6 sigma time period variation (peak to peak) | –500 | +500 | ps |
| F_{free} | PLL free running frequency | Multiplication Factors: 3, 4 Multiplication Factors: 5, 8, 10, 16 | 250 500 | 2000 4000 | kHz |

1. Not 100% tested, guaranteed by design characterization.

24.8.11 Main oscillator specifications

$V_{DD} = 5V \pm 10\%$, $V_{SS} = 0V$, $T_A = -40$ to $+125^\circ C$

Table 72. Main oscillator characteristics

| Symbol | Parameter | Conditions | Value | | | Unit |
|------------|---|-----------------------------|-------|------|------|------|
| | | | min. | typ. | max. | |
| g_m | Oscillator Transconductance | | 1.4 | 2.6 | 4.2 | mA/V |
| V_{OSC} | Oscillation Amplitude ¹⁾ | Peak to Peak | – | 1.5 | – | V |
| V_{AV} | Oscillation Voltage level ¹⁾ | Sine wave middle | – | 0.8 | – | V |
| t_{STUP} | Oscillator Start-up Time ¹⁾ | Stable V_{DD} - Crystal | – | 6 | 10 | ms |
| | | Stable V_{DD} - Resonator | – | 1 | 2 | ms |

1. Not 100% tested, guaranteed by design characterization.

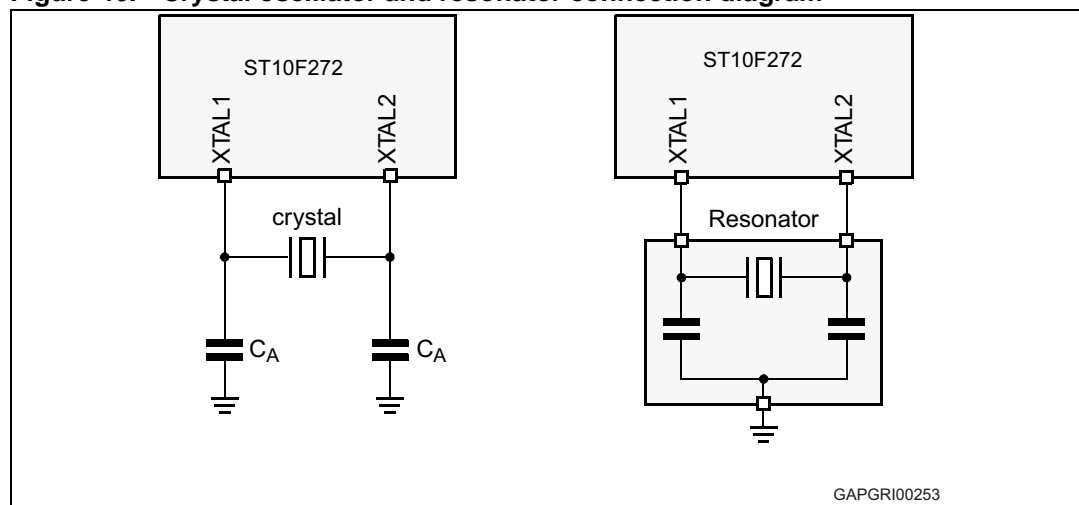

Figure 46. Crystal oscillator and resonator connection diagram

Table 73. Main oscillator negative resistance (module)

| | $C_A = 15\text{pF}$ | | | $C_A = 25\text{pF}$ | | | $C_A = 35\text{pF}$ | | |
|--------------|---------------------|---------------|------|---------------------|---------------|------|---------------------|--------------|------|
| | min. | typ. | max. | min. | typ. | max. | min. | typ. | max. |
| 4 MHz | 545 Ω | 1035 Ω | – | 550 Ω | 1050 Ω | – | 430 Ω | 850 Ω | – |
| 8 MHz | 240 Ω | 450 Ω | – | 170 Ω | 350 Ω | – | 120 Ω | 250 Ω | – |

The given values of C_A do not include the stray capacitance of the package and of the printed circuit board: the negative resistance values are calculated assuming additional 5pF to the values in the table. The crystal shunt capacitance (C_0) and the package capacitance between XTAL1 and XTAL2 pins is globally assumed equal to 10pF.

The external resistance between XTAL1 and XTAL2 is not necessary, since already present on the silicon.

24.8.12 32 kHz oscillator specifications

$V_{DD} = 5V \pm 10\%$, $V_{SS} = 0V$, $T_A = -40$ to $+125^\circ\text{C}$

Table 74. 32kHz oscillator characteristics

| Symbol | Parameter | Conditions | Value | | | Unit |
|--------------------------------|---|------------------|-------|------|------|-----------------|
| | | | min. | typ. | max. | |
| g_{m32} | Oscillator Transconductance ¹⁾ | Start-up | 20 | 31 | 50 | $\mu\text{A/V}$ |
| | | Normal run | 8 | 17 | 30 | $\mu\text{A/V}$ |
| V_{OSC32} | Oscillation Amplitude ²⁾ | Peak to Peak | 0.5 | 1.0 | 2.4 | V |
| V_{AV32} | Oscillation Voltage level ²⁾ | Sine wave middle | 0.7 | 0.9 | 1.2 | V |
| t_{STUP32} | Oscillator Start-up Time ²⁾ | Stable V_{DD} | – | 1 | 5 | s |

1. At power-on a high current biasing is applied for faster oscillation start-up. Once the oscillation is started, the current biasing is reduced to lower the power consumption of the system.
2. Not 100% tested, guaranteed by design characterization.

Figure 47. 32kHz crystal oscillator connection diagram

Table 75. Minimum values of negative resistance (module) for 32kHz oscillator

| | $C_A = 6\text{pF}$ | $C_A = 12\text{pF}$ | $C_A = 15\text{pF}$ | $C_A = 18\text{pF}$ | $C_A = 22\text{pF}$ | $C_A = 27\text{pF}$ | $C_A = 33\text{pF}$ |
|-------|--------------------|---------------------|---------------------|---------------------|---------------------|---------------------|---------------------|
| 32kHz | - | - | - | - | 150 k Ω | 120 k Ω | 90 k Ω |

The given values of C_A do not include the stray capacitance of the package and of the printed circuit board: the negative resistance values are calculated assuming additional 5pF to the values in the table. The crystal shunt capacitance (C_0) and the package capacitance between XTAL3 and XTAL4 pins is globally assumed equal to 4pF. The external resistance between XTAL3 and XTAL4 is not necessary, since already present on the silicon.

Warning: Direct driving on XTAL3 pin is not supported. Always use a 32kHz crystal oscillator.

24.8.13 External clock drive XTAL1

When Direct Drive configuration is selected during reset, it is possible to drive the CPU clock directly from the XTAL1 pin, without particular restrictions on the maximum frequency, since the on-chip oscillator amplifier is bypassed. The speed limit is imposed by internal logic that targets a maximum CPU frequency of 64MHz.

In all other clock configurations (Direct Drive with Prescaler or PLL usage) the on-chip oscillator amplifier is not bypassed, so it determines the input clock speed limit. Then, when the on-chip oscillator is enabled it is forbidden to use any external clock source different from crystal or ceramic resonator.

Table 76. External clock drive

| Parameter | Symbol | Direct drive $f_{CPU} = f_{XTAL}$ | | Direct drive with prescaler $f_{CPU} = f_{XTAL} / 2$ | | PLL usage $f_{CPU} = f_{XTAL} \times F$ | | Unit |
|------------------------------|--------------|--------------------------------------|------|--|------|--|------|------|
| | | min. | max. | min. | max. | min. | max. | |
| XTAL1 period ^{1, 2} | t_{OSC} SR | 15.625 | — | 83.3 | 250 | 83.3 | 250 | ns |
| High time ³ | t_1 SR | 6 | — | 3 | — | 6 | — | ns |
| Low time ³ | t_2 SR | 6 | — | 3 | — | 6 | — | ns |
| Rise time ³ | t_3 SR | — | 2 | — | 2 | — | 2 | ns |
| Fall time ³ | t_4 SR | — | 2 | — | 2 | — | 2 | ns |

1. The minimum value for the XTAL1 signal period shall be considered as the theoretical minimum. The real minimum value depends on the duty cycle of the input clock signal.
2. 4-8 MHz is the input frequency range when using an external clock source. 64 MHz can be applied with an external clock source only when Direct Drive mode is selected: in this case, the oscillator amplifier is bypassed so it does not limit the input frequency.
3. The input clock signal must reach the defined levels V_{IL2} and V_{IH2} .

Figure 48. External clock drive XTAL1

Note: When Direct Drive is selected, an external clock source can be used to drive XTAL1. The maximum frequency of the external clock source depends on the duty cycle: when 64MHz is used, 50% duty cycle shall be granted (low phase = high phase = 7.8ns); when for instance 32MHz is used, a 25% duty cycle can be accepted (minimum phase, high or low, again equal to 7.8ns).

24.8.14 Memory cycle variables

The tables below use three variables which are derived from the BUSCONx registers and represent the special characteristics of the programmed memory cycle. [Table 77](#) describes, how these variables are to be computed.

Table 77. Memory cycle variables

| Description | Symbol | Values |
|-------------------------------|--------|-----------------------------|
| ALE Extension | t_A | $TCL \times [ALECTL]$ |
| Memory Cycle Time wait states | t_C | $2TCL \times (15 - [MCTC])$ |
| Memory Tri-state Time | t_F | $2TCL \times (1 - [MTTC])$ |

24.8.15 External memory bus timing

The following sections include the External Memory Bus timings. The given values are computed for a maximum CPU clock of 40MHz.

Obviously, when higher CPU clock frequency is used (up to 64MHz), some numbers in the timing formulas become zero or negative which, in most cases is not acceptable or not meaningless at all. In these cases, it is necessary to relax the speed of the bus setting properly t_A , t_C and t_F .

Note: All External Memory Bus Timings and SSC Timings reported in the following tables are granted by Design Characterization and not fully tested in production.

24.8.16 Multiplexed bus

$V_{DD} = 5V \pm 10\%$, $V_{SS} = 0V$, $T_A = -40$ to $+125^\circ\text{C}$, $CL = 50\text{pF}$,
 ALE cycle time = $6\text{ TCL} + 2t_A + t_C + t_F$ (75ns at 40MHz CPU clock without wait states)

Table 78. Multiplexed bus timings

| Symbol | Parameter | $F_{CPU} = 40\text{ MHz}$ $TCL = 12.5\text{ ns}$ | | Variable CPU Clock $1/2\text{ TCL} = 1\text{ to }64\text{MHz}$ | | Unit |
|-------------|--|---|--------------------|---|--------------------------|------|
| | | min. | max. | min. | max. | |
| t_5 CC | ALE high time | $4 + t_A$ | — | $TCL - 8.5 + t_A$ | — | ns |

The diagram illustrates the timing for Read and Write cycles of the 68000 microprocessor. It shows the relationship between the Address/Data bus (P0), the Read/Write control signals (\overline{RD} , \overline{WR}), and the Address/Status bus (A23-A16, BHE). The timing parameters are defined as follows:

- t_1 : Address setup time before \overline{RD} or \overline{WR} goes active.
- t_2 : Address hold time after \overline{RD} or \overline{WR} goes active.
- t_3 : Address setup time before \overline{RD} or \overline{WR} goes active (for the second cycle).
- t_4 : Address hold time after \overline{RD} or \overline{WR} goes active (for the second cycle).
- t_5 : Address setup time before \overline{RD} or \overline{WR} goes active (for the third cycle).
- t_6 : Address hold time after \overline{RD} or \overline{WR} goes active (for the third cycle).
- t_7 : Address setup time before \overline{RD} or \overline{WR} goes active (for the fourth cycle).
- t_8 : Address hold time after \overline{RD} or \overline{WR} goes active (for the fourth cycle).
- t_9 : Address setup time before \overline{RD} or \overline{WR} goes active (for the fifth cycle).
- t_{10} : Address hold time after \overline{RD} or \overline{WR} goes active (for the fifth cycle).
- t_{11} : Address setup time before \overline{RD} or \overline{WR} goes active (for the sixth cycle).
- t_{12} : Address hold time after \overline{RD} or \overline{WR} goes active (for the sixth cycle).
- t_{13} : Address setup time before \overline{RD} or \overline{WR} goes active (for the seventh cycle).
- t_{14} : Address hold time after \overline{RD} or \overline{WR} goes active (for the seventh cycle).
- t_{15} : Address setup time before \overline{RD} or \overline{WR} goes active (for the eighth cycle).
- t_{16} : Address hold time after \overline{RD} or \overline{WR} goes active (for the eighth cycle).
- t_{17} : Address setup time before \overline{RD} or \overline{WR} goes active (for the ninth cycle).
- t_{18} : Address hold time after \overline{RD} or \overline{WR} goes active (for the ninth cycle).
- t_{19} : Address setup time before \overline{RD} or \overline{WR} goes active (for the tenth cycle).
- t_{20} : Address hold time after \overline{RD} or \overline{WR} goes active (for the tenth cycle).
- t_{21} : Address setup time before \overline{RD} or \overline{WR} goes active (for the eleventh cycle).
- t_{22} : Address hold time after \overline{RD} or \overline{WR} goes active (for the eleventh cycle).
- t_{23} : Address setup time before \overline{RD} or \overline{WR} goes active (for the twelfth cycle).
- t_{24} : Address hold time after \overline{RD} or \overline{WR} goes active (for the twelfth cycle).
- t_{25} : Address setup time before \overline{RD} or \overline{WR} goes active (for the thirteenth cycle).
- t_{26} : Address hold time after \overline{RD} or \overline{WR} goes active (for the thirteenth cycle).
- t_{27} : Address setup time before \overline{RD} or \overline{WR} goes active (for the fourteenth cycle).
- t_{28} : Address hold time after \overline{RD} or \overline{WR} goes active (for the fourteenth cycle).
- t_{29} : Address setup time before \overline{RD} or \overline{WR} goes active (for the fifteenth cycle).
- t_{30} : Address hold time after \overline{RD} or \overline{WR} goes active (for the fifteenth cycle).
- t_{31} : Address setup time before \overline{RD} or \overline{WR} goes active (for the sixteenth cycle).
- t_{32} : Address hold time after \overline{RD} or \overline{WR} goes active (for the sixteenth cycle).
- t_{33} : Address setup time before \overline{RD} or \overline{WR} goes active (for the seventeenth cycle).
- t_{34} : Address hold time after \overline{RD} or \overline{WR} goes active (for the seventeenth cycle).
- t_{35} : Address setup time before \overline{RD} or \overline{WR} goes active (for the eighteenth cycle).
- t_{36} : Address hold time after \overline{RD} or \overline{WR} goes active (for the eighteenth cycle).
- t_{37} : Address setup time before \overline{RD} or \overline{WR} goes active (for the nineteenth cycle).
- t_{38} : Address hold time after \overline{RD} or \overline{WR} goes active (for the nineteenth cycle).
- t_{39} : Address setup time before \overline{RD} or \overline{WR} goes active (for the twentieth cycle).
- t_{40} : Address hold time after \overline{RD} or \overline{WR} goes active (for the twentieth cycle).

| t ₈₃ CC | Address setup to $\overline{\text{RdCS}}$, $\overline{\text{WrCS}}$ (no RW-delay) | $2 + 2t_A$ | – | $TCL - 10.5 + 2t_A$ | – | ns |
| t ₄₆ SR | $\overline{\text{RdCS}}$ to Valid Data In (with RW-delay) | – | $4 + t_C$ | – | $2TCL - 21 + t_C$ | ns |
| t ₄₇ SR | $\overline{\text{RdCS}}$ to Valid Data In (no RW-delay) | – | $16.5 + t_C$ | – | $3TCL - 21 + t_C$ | ns |
| t ₄₈ CC | $\overline{\text{RdCS}}$, $\overline{\text{WrCS}}$ Low Time (with RW-delay) | $15.5 + t_C$ | – | $2TCL - 9.5 + t_C$ | – | ns |
| t ₄₉ CC | $\overline{\text{RdCS}}$, $\overline{\text{WrCS}}$ Low Time (no RW-delay) | $28 + t_C$ | – | $3TCL - 9.5 + t_C$ | – | ns |
| t ₅₀ CC | Data valid to $\overline{\text{WrCS}}$ | $10 + t_C$ | – | $2TCL - 15 + t_C$ | – | ns |
| t ₅₁ SR | Data hold after $\overline{\text{RdCS}}$ | 0 | – | 0 | – | ns |
| t ₅₃ SR | Data float after $\overline{\text{RdCS}}$ (with RW-delay) | – | $16.5 + t_F$ | – | $2TCL - 8.5 + t_F$ | ns |
| t ₆₈ SR | Data float after $\overline{\text{RdCS}}$ (no RW-delay) | – | $4 + t_F$ | – | $TCL - 8.5 + t_F$ | ns |
| t ₅₅ CC | Address hold after $\overline{\text{RdCS}}$, $\overline{\text{WrCS}}$ | $-8.5 + t_F$ | – | $-8.5 + t_F$ | – | ns |
| t ₅₇ CC | Data hold after $\overline{\text{WrCS}}$ | $2 + t_F$ | – | $TCL - 10.5 + t_F$ | – | ns |

1. RW-delay and t_A refer to the next following bus cycle.
2. Read data are latched with the same clock edge that triggers the address change and the rising $\overline{\text{RD}}$ edge. Therefore address changes before the end of $\overline{\text{RD}}$ have no impact on read cycles.
3. Partially tested, guaranteed by design characterization.

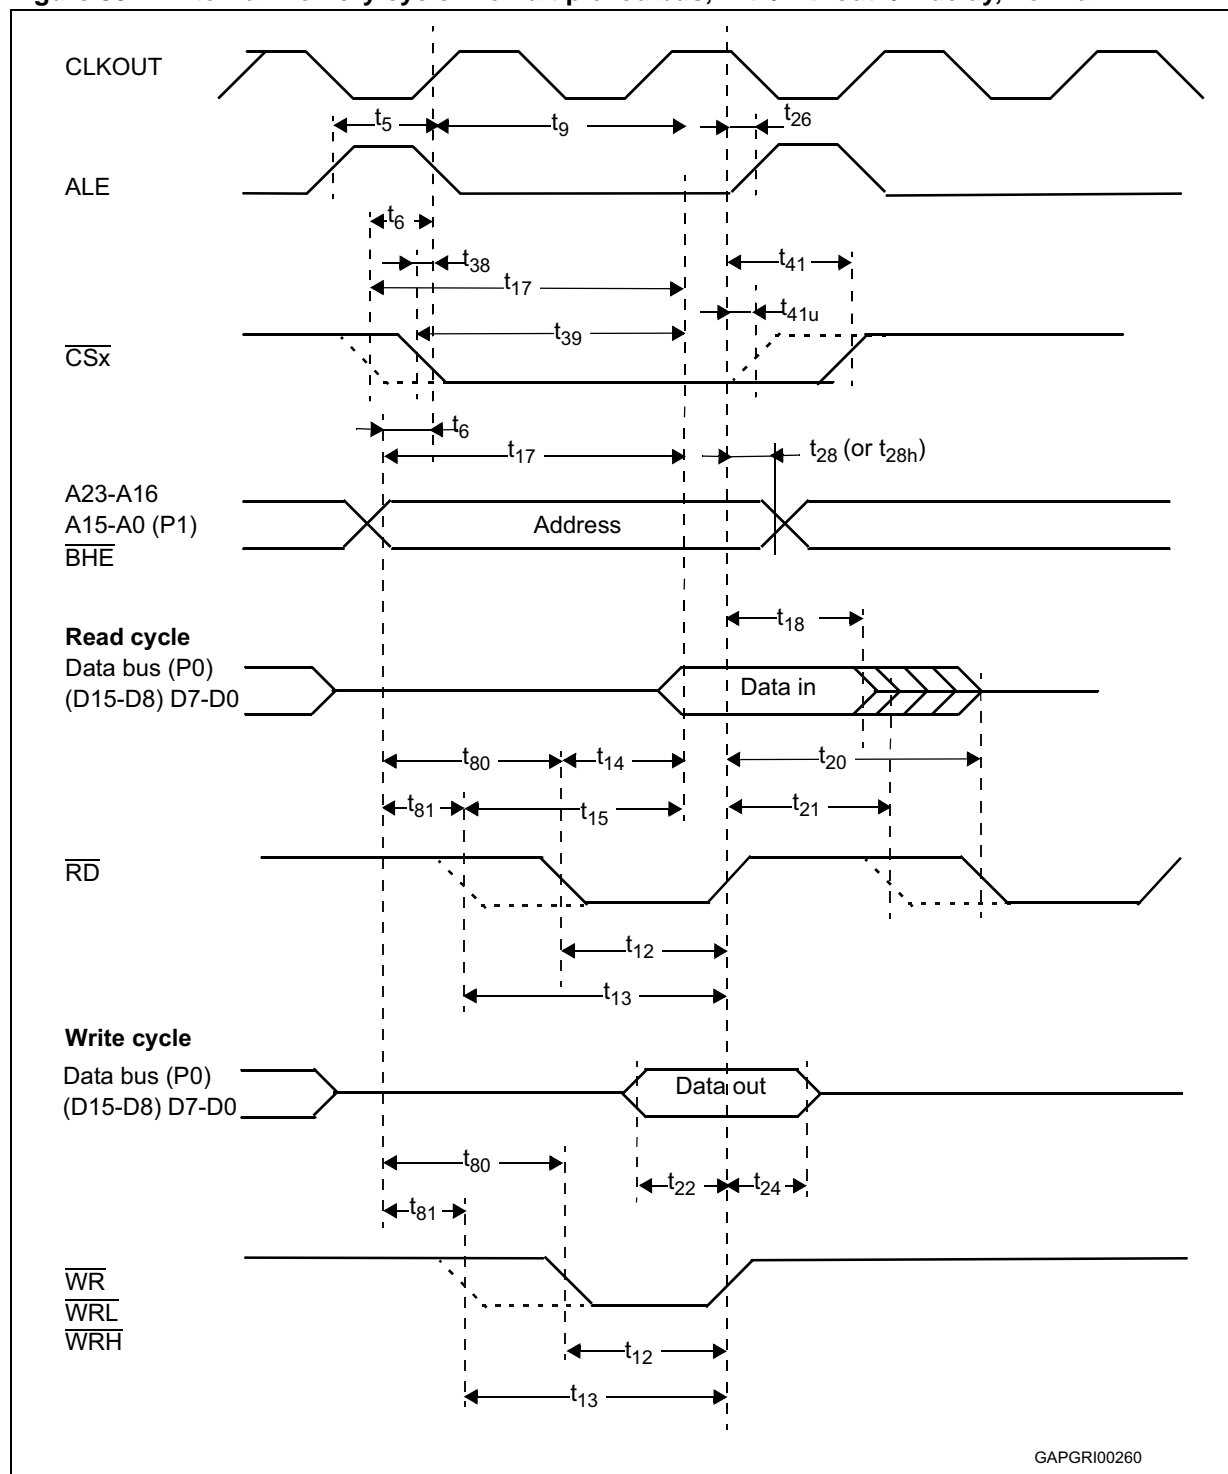

Figure 53. External memory cycle: Demultiplexed bus, with/without r/w delay, normal ALE

Figure 54. External memory cycle: Demultiplexed bus, with/without r/w delay, extended ALE

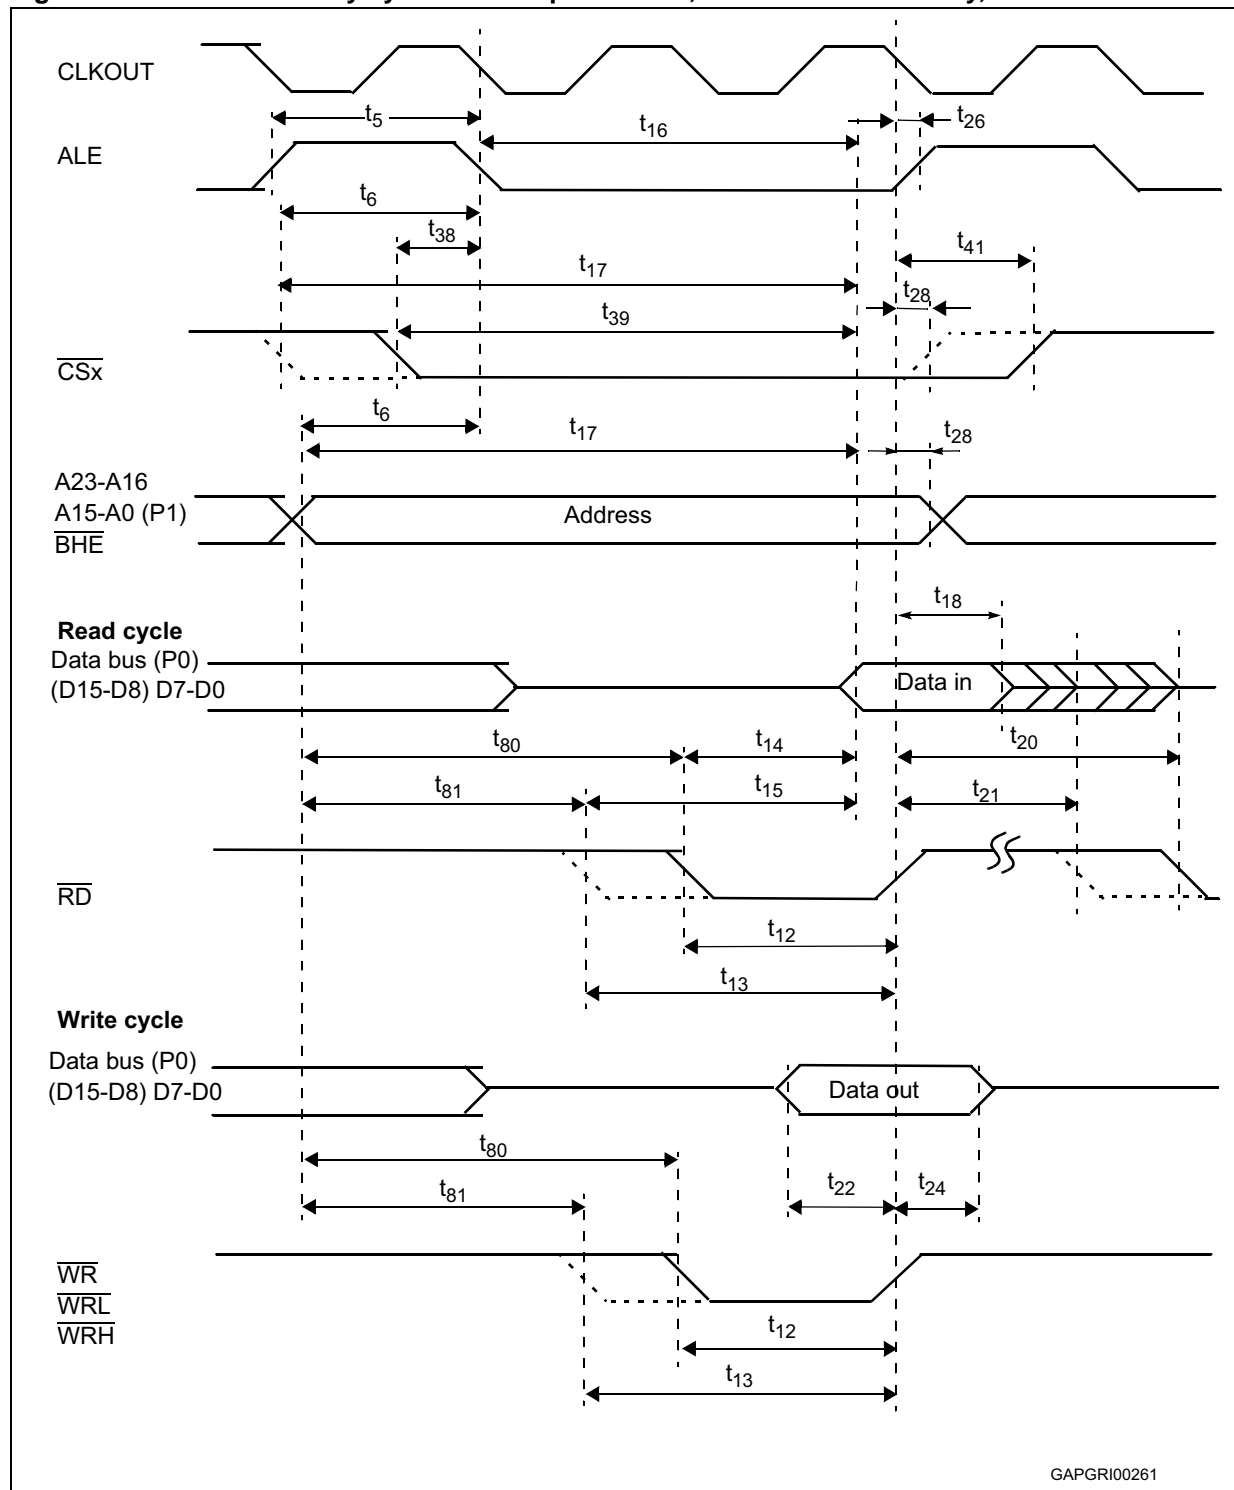

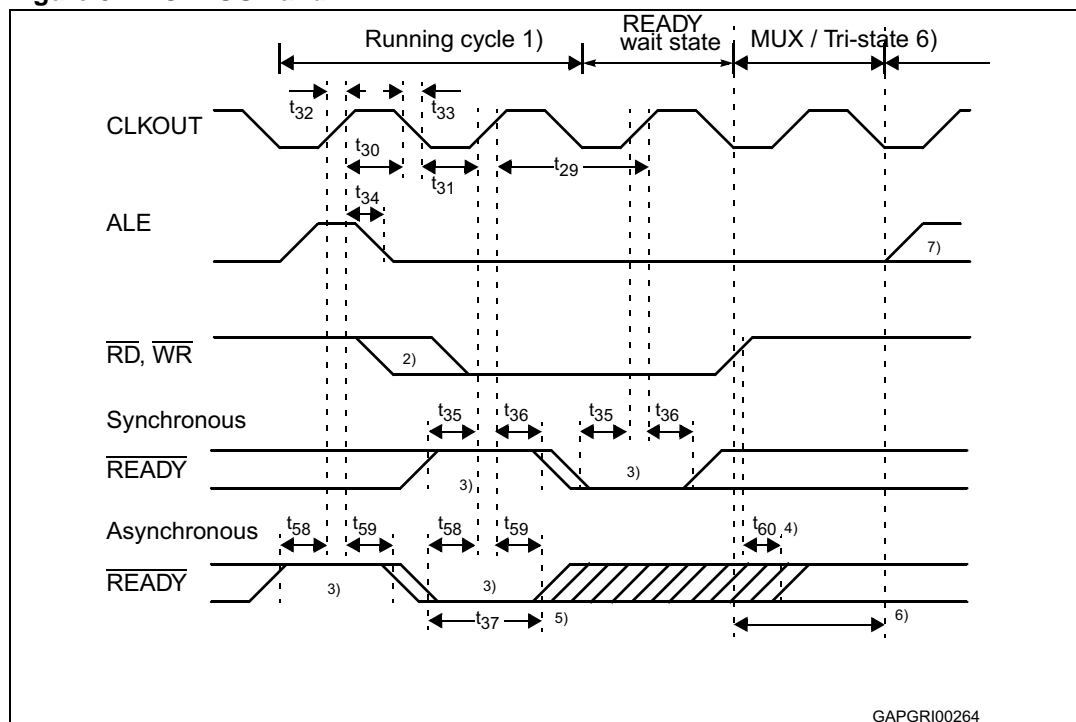

Figure 55. External memory cycle: Demultipl. bus, with/without r/w delay, normal ALE, r/w CS

Figure 56. External memory cycle: Demultiplexed bus, without r/w delay, extended ALE, r/w CS

24.8.18 CLKOUT and $\overline{\text{READY}}$
 $V_{DD} = 5V \pm 10\%$, $V_{SS} = 0V$, $T_A = -40$ to $+125^\circ\text{C}$, $CL = 50\text{pF}$
Table 80. CLKOUT and $\overline{\text{READY}}$ timings

| Symbol | Parameter | $F_{CPU} = 40\text{ MHz}$ $TCL = 12.5\text{ ns}$ | | Variable CPU Clock 1/2 $TCL = 1$ to 64MHz | | Unit |
|--------------------|--|---|--------------------|---|--------------------|------|
| | | min. | max. | min. | max. | |
| t_{29} CC | CLKOUT cycle time | 25 | 25 | 2TCL | 2TCL | ns |
| t_{30} CC | CLKOUT high time | 9 | – | $TCL - 3.5$ | – | ns |
| t_{31} CC | CLKOUT low time | 10 | – | $TCL - 2.5$ | – | ns |
| t_{32} CC | CLKOUT rise time | – | 4 | – | 4 | ns |
| t_{33} CC | CLKOUT fall time | – | 4 | – | 4 | ns |
| t_{34} CC | CLKOUT rising edge to ALE falling edge | $-2 + t_A$ | $8 + t_A$ | $-2 + t_A$ | $8 + t_A$ | ns |
| t_{35} SR | Synchronous $\overline{\text{READY}}$ setup time to CLKOUT | 17 | – | 17 | – | ns |
| t_{36} SR | Synchronous $\overline{\text{READY}}$ hold time after CLKOUT | 2 | – | 2 | – | ns |
| t_{37} SR | Asynchronous $\overline{\text{READY}}$ low time | 35 | – | $2TCL + 10$ | – | ns |
| t_{58} SR | Asynchronous $\overline{\text{READY}}$ setup time ¹ | 17 | – | 17 | – | ns |
| t_{59} SR | Asynchronous $\overline{\text{READY}}$ hold time ¹ | 2 | – | 2 | – | ns |
| t_{60} SR | Async. $\overline{\text{READY}}$ hold time after $\overline{\text{RD}}$, $\overline{\text{WR}}$ high (Demultiplexed Bus) ² | 0 | $2t_A + t_C + t_F$ | 0 | $2t_A + t_C + t_F$ | ns |

1. These timings are given for characterization purposes only, in order to assure recognition at a specific clock edge.
2. Demultiplexed bus is the worst case. For multiplexed bus 2TCL are to be added to the maximum values. This adds even more time for deactivating $\overline{\text{READY}}$. $2t_A$ and t_C refer to the next following bus cycle, t_F refers to the current bus cycle.

Figure 57. CLKOUT and $\overline{\text{READY}}$ 

GAPGRI00264

1. Cycle as programmed, including MCTC wait states (Example shows 0 MCTC WS).
2. The leading edge of the respective command depends on RW-delay.
3. $\overline{\text{READY}}$ sampled HIGH at this sampling point generates a $\overline{\text{READY}}$ controlled wait state, $\overline{\text{READY}}$ sampled LOW at this sampling point terminates the currently running bus cycle.
4. $\overline{\text{READY}}$ may be deactivated in response to the trailing (rising) edge of the corresponding command ($\overline{\text{RD}}$ or $\overline{\text{WR}}$).
5. If the Asynchronous $\overline{\text{READY}}$ signal does not fulfill the indicated setup and hold times with respect to CLKOUT (e.g. because CLKOUT is not enabled), it must fulfill t_{37} in order to be safely synchronized. This is guaranteed, if $\overline{\text{READY}}$ is removed in response to the command (see Note 4).
6. Multiplexed bus modes have a MUX wait state added after a bus cycle, and an additional MTTC wait state may be inserted here.
For a multiplexed bus with MTTC wait state this delay is two CLKOUT cycles, for a demultiplexed bus without MTTC wait state this delay is zero.
7. The next external bus cycle may start here.

24.8.19 External bus arbitration

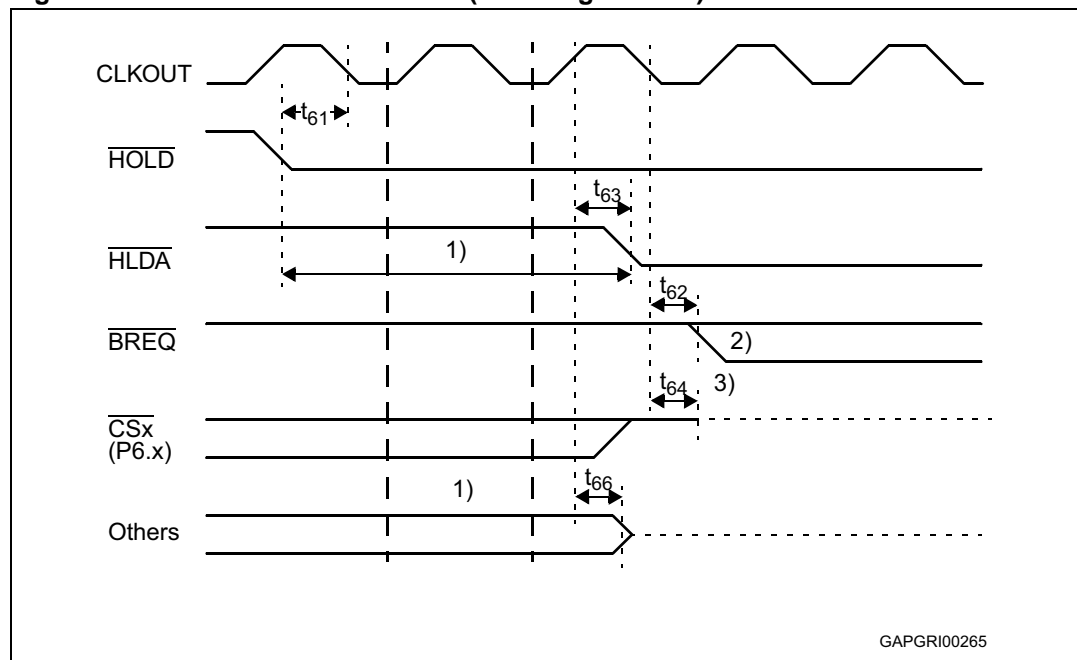

$V_{DD} = 5V \pm 10\%$, $V_{SS} = 0V$, $T_A = -40$ to $+125^\circ\text{C}$, $C_L = 50\text{pF}$

Table 81. External bus arbitration timings

| Symbol | Parameter | $F_{CPU} = 40\text{ MHz}$ $TCL = 12.5\text{ ns}$ | | Variable CPU Clock 1/2 $TCL = 1$ to 64MHz | | Unit |
|--------------------|---|---|------|---|------|------|
| | | min. | max. | min. | max. | |
| t_{61} SR | \overline{HOLD} input setup time to CLKOUT | 18.5 | – | 18.5 | – | ns |
| t_{62} CC | CLKOUT to \overline{HLDA} high or \overline{BREQ} low delay | – | 12.5 | – | 12.5 | ns |
| t_{63} CC | CLKOUT to \overline{HLDA} low or \overline{BREQ} high delay | – | 12.5 | – | 12.5 | ns |
| t_{64} CC | \overline{CSx} release ¹⁾ | – | 20 | – | 20 | ns |
| t_{65} CC | \overline{CSx} drive | – 4 | 15 | – 4 | 15 | ns |
| t_{66} CC | Other signals release ¹⁾ | – | 20 | – | 20 | ns |
| t_{67} CC | Other signals drive | – 4 | 15 | – 4 | 15 | ns |

1. Partially tested, guaranteed by design characterization.

Figure 58. External bus arbitration (releasing the bus)

1. The ST10F272 will complete the currently running bus cycle before granting bus access.
2. This is the first possibility for \overline{BREQ} to become active.
3. The \overline{CS} outputs will be resistive high (pull-up) after t_{64} .

Figure 59. External bus arbitration (regaining the bus)

GAPGRI00266

1. This is the last chance for $\overline{\text{BREQ}}$ to trigger the indicated regain-sequence. Even if $\overline{\text{BREQ}}$ is activated earlier, the regain-sequence is initiated by $\overline{\text{HOLD}}$ going high. Please note that $\overline{\text{HOLD}}$ may also be deactivated without the ST10F272 requesting the bus.
2. The next ST10F272 driven bus cycle may start here.

24.8.20 High-speed synchronous serial interface (SSC) timing

24.8.20.1 Master mode

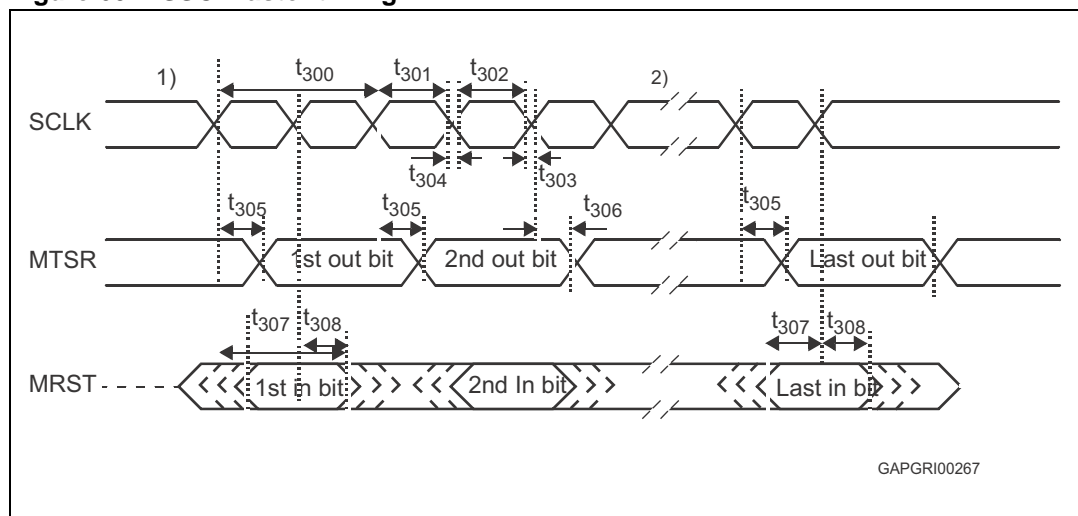

$V_{DD} = 5V \pm 10\%$, $V_{SS} = 0V$, $T_A = -40$ to $+125^\circ C$, $C_L = 50pF$

Table 82. SSC master mode timings

| Symbol | | Parameter | Max. Baudrate 6.6MBd (¹)@F _{CPU} = 40MHz (<SSCBR> = 0002h) | | Variable Baudrate (<SSCBR> = 0001h - FFFFh) | | Unit |
|-------------------|----|--|--|------|--|------------|------|
| | | | min. | max. | min. | max. | |
| t ₃₀₀ | CC | SSC clock cycle time ⁽²⁾ | 150 | 150 | 8TCL | 262144 TCL | ns |
| t ₃₀₁ | CC | SSC clock high time | 63 | – | t ₃₀₀ / 2 – 12 | – | ns |
| t ₃₀₂ | CC | SSC clock low time | 63 | – | t ₃₀₀ / 2 – 12 | – | ns |
| t ₃₀₃ | CC | SSC clock rise time | – | 10 | – | 10 | ns |
| t ₃₀₄ | CC | SSC clock fall time | – | 10 | – | 10 | ns |
| t ₃₀₅ | CC | Write data valid after shift edge | – | 15 | – | 15 | ns |
| t ₃₀₆ | CC | Write data hold after shift edge ⁽³⁾ | – 2 | – | – 2 | – | ns |
| t _{307p} | SR | Read data setup time before latch edge, phase error detection on (SSCPEN = 1) | 37.5 | – | 2TCL + 12.5 | – | ns |
| t _{308p} | SR | Read data hold time after latch edge, phase error detection on (SSCPEN = 1) | 50 | – | 4TCL | – | ns |
| t ₃₀₇ | SR | Read data setup time before latch edge, phase error detection off (SSCPEN = 0) | 25 | – | 2TCL | – | ns |
| t ₃₀₈ | SR | Read data hold time after latch edge, phase error detection off (SSCPEN = 0) | 0 | – | 0 | – | ns |

1. Maximum Baudrate is in reality 8Mbaud, that can be reached with 64MHz CPU clock and <SSCBR> set to '3h', or with 48MHz CPU clock and <SSCBR> set to '2h'. When 40MHz CPU clock is used the maximum baudrate cannot be higher than 6.6Mbaud (<SSCBR> = '2h') due to the limited granularity of <SSCBR>. Value '1h' for <SSCBR> can be used only with CPU clock equal to (or lower than) 32MHz.
2. Formula for SSC Clock Cycle time: t₃₀₀ = 4 TCL x (<SSCBR> + 1) Where <SSCBR> represents the content of the SSC Baudrate register, taken as unsigned 16-bit integer. Minimum limit allowed for t₃₀₀ is 125ns (corresponding to 8Mbaud).
3. Partially tested, guaranteed by design characterization.

Figure 60. SSC master timing

1. The phase and polarity of shift and latch edge of SCLK is programmable. *Figure 60* uses the leading clock edge as shift edge (drawn in bold), with latch on trailing edge (SSCPH = 0b). Idle clock line is low, leading clock edge is low-to-high transition (SSCPO = 0b).
2. The bit timing is repeated for all bits to be transmitted or received.

24.8.20.2 Slave mode

$V_{DD} = 5V \pm 10\%$, $V_{SS} = 0V$, $T_A = -40$ to $+125^\circ C$, $C_L = 50pF$

Table 83. SSC slave mode timings

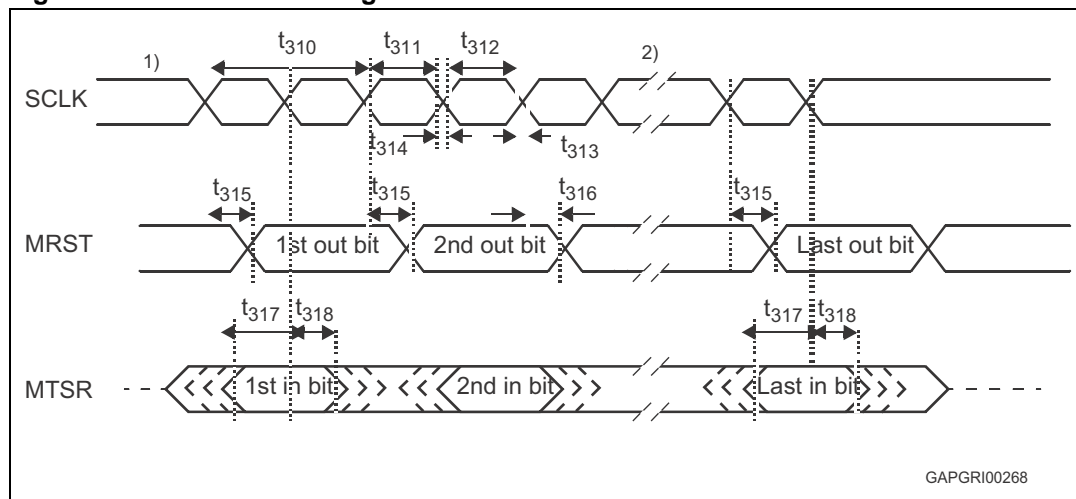

| Symbol | | Parameter | Max. Baudrate 6.6 MBd ⁽¹⁾ @F _{CPU} = 40MHz (<SSCBR> = 0002h) | | Variable Baudrate (<SSCBR> = 0001h - FFFFh) | | Unit |
|-------------------|----|---|---|------|--|------------|------|
| | | | min. | max. | min. | max. | |
| t ₃₁₀ | SR | SSC clock cycle time ⁽²⁾ | 150 | 150 | 8TCL | 262144 TCL | ns |
| t ₃₁₁ | SR | SSC clock high time | 63 | — | t ₃₁₀ / 2 – 12 | — | ns |
| t ₃₁₂ | SR | SSC clock low time | 63 | — | t ₃₁₀ / 2 – 12 | — | ns |
| t ₃₁₃ | SR | SSC clock rise time | — | 10 | — | 10 | ns |
| t ₃₁₄ | SR | SSC clock fall time | — | 10 | — | 10 | ns |
| t ₃₁₅ | CC | Write data valid after shift edge | — | 55 | — | 2TCL + 30 | ns |
| t ₃₁₆ | CC | Write data hold after shift edge | 0 | — | 0 | — | ns |
| t _{317p} | SR | Read data setup time before latch edge, phase error detection on (SSCPEN = 1) | 62 | — | 4TCL + 12 | — | ns |
| t _{318p} | SR | Read data hold time after latch edge, phase error detection on (SSCPEN = 1) | 87 | — | 6TCL + 12 | — | ns |

Table 83. SSC slave mode timings (continued)

| Symbol | Parameter | Max. Baudrate 6.6 MBd ⁽¹⁾ @F _{CPU} = 40MHz (<SSCBR> = 0002h) | | Variable Baudrate (<SSCBR> = 0001h - FFFFh) | | Unit |
|------------------|---|---|------|---|------|------|
| | | min. | max. | min. | max. | |
| t ₃₁₇ | SR Read data setup time before latch edge, phase error detection off (SSCPEN = 0) | 6 | — | 6 | — | ns |
| t ₃₁₈ | SR Read data hold time after latch edge, phase error detection off (SSCPEN = 0) | 31 | — | 2TCL + 6 | — | ns |

- Maximum Baudrate is in reality 8Mbaud, that can be reached with 64MHz CPU clock and <SSCBR> set to '3h', or with 48MHz CPU clock and <SSCBR> set to '2h'. When 40MHz CPU clock is used the maximum baudrate cannot be higher than 6.6Mbaud (<SSCBR> = '2h') due to the limited granularity of <SSCBR>. Value '1h' for <SSCBR> may be used only with CPU clock lower than 32MHz (after checking that resulting timings are suitable for the master).
- Formula for SSC Clock Cycle time: $t_{310} = 4 \text{ TCL} * (<\text{SSCBR}> + 1)$
Where <SSCBR> represents the content of the SSC Baudrate register, taken as unsigned 16-bit integer.
Minimum limit allowed for t₃₁₀ is 125ns (corresponding to 8Mbaud).

Figure 61. SSC slave timing

- The phase and polarity of shift and latch edge of SCLK is programmable. [Figure 61](#) uses the leading clock edge as shift edge (drawn in bold), with latch on trailing edge (SSCPH = 0b). Idle clock line is low, leading clock edge is low-to-high transition (SSCPO = 0b).
- The bit timing is repeated for all bits to be transmitted or received.

25 Package information

To meet environmental requirements, ST offers these devices in different grades of ECOPACK® packages, depending on their level of environmental compliance. ECOPACK® specifications, grade definitions, and product status are available at www.st.com. ECOPACK® is an ST trademark.
