

250 MHz Bandwidth DPD Observation Receiver

AD6641

FEATURES

SNR = 65.8 dBFS at f_{IN} up to 250 MHz at 500 MSPS ENOB of 10.5 bits at f_{IN} up to 250 MHz at 500 MSPS (-1.0 dBFS) SFDR = 80 dBc at f_{IN} up to 250 MHz at 500 MSPS (-1.0 dBFS) **Excellent linearity** DNL = ± 0.5 LSB typical, INL = ± 0.6 LSB typical Integrated 16k × 12 FIFO **FIFO readback options** 12-bit parallel CMOS at 62.5 MHz 6-bit DDR LVDS interface SPORT at 62.5 MHz SPI at 25 MHz High speed synchronization capability 1 GHz full power analog bandwidth Integrated input buffer On-chip reference, no external decoupling required Low power dissipation 695 mW at 500 MSPS Programmable input voltage range 1.18 V to 1.6 V, 1.5 V nominal 1.9 V analog and digital supply operation 1.9 V or 3.3 V SPI and SPORT operation Clock duty cycle stabilizer Integrated data clock output with programmable clock and data alignment

APPLICATIONS

Wireless and wired broadband communications Communications test equipment Power amplifier linearization

GENERAL DESCRIPTION

The AD6641 is a 250 MHz bandwidth digital predistortion (DPD) observation receiver that integrates a 12-bit 500 MSPS ADC, a 16k \times 12 FIFO, and a multimode back end that allows users to retrieve the data through a serial port (SPORT), the SPI interface, a 12-bit parallel CMOS port, or a 6-bit DDR LVDS port after being stored in the integrated FIFO memory. It is optimized for outstanding dynamic performance and low power consumption and is suitable for use in telecommunications applications such as a digital predistortion observation path where wider bandwidths are desired. All necessary functions, including the sample-and-hold and voltage reference, are included on the chip to provide a complete signal conversion solution.

The on-chip FIFO allows small snapshots of time to be captured via the ADC and read back at a lower rate. This reduces the constraints of signal processing by transferring the captured data at an arbitrary time and at a much lower sample rate. The FIFO can be operated in several user-programmable modes. In the single capture mode, the ADC data is captured when signaled via the SPI port or the use of the external FILL± pins. In the continuous capture mode, the data is loaded continuously into the FIFO and the FILL± pins are used to stop this operation.

The data stored in the FIFO can be read back based on several user-selectable output modes. The DUMP pin can be asserted to output the FIFO data. The data stored in the FIFO can be accessed via a SPORT, SPI, 12-bit parallel CMOS port, or 6-bit DDR LVDS interface. The maximum output throughput supported by the AD6641 is in the 12-bit CMOS or 6-bit DDR LVDS mode and is internally limited to 1/8th of the maximum input sample rate. This corresponds to the maximum output data rate of 62.5 MHz at an input clock rate of 500 MSPS.

The ADC requires a 1.9 V analog voltage supply and a differential clock for full performance operation. Output format options include twos complement, offset binary format, or Gray code. A data clock output is available for proper output data timing. Fabricated on an advanced SiGe BiCMOS process, the device is available in a 56-lead LFCSP and is specified over the industrial temperature range (-40° C to $+85^{\circ}$ C). This product is protected by a U.S. patent.

PRODUCT HIGHLIGHTS

- 1. High Performance ADC Core. Maintains 65.8 dBFS SNR at 500 MSPS with a 250 MHz input.
- 2. Low Power.
- Consumes only 695 mW at 500 MSPS.
- 3. Ease of Use.
 - On-chip 16k FIFO allows the user to target the high performance ADC to the time period of interest and reduce the constraints of processing the data by transferring it at an arbitrary time and a lower sample rate. The on-chip reference and sample-and-hold provide flexibility in system design. Use of a single 1.9 V supply simplifies system power supply design.
- Serial Port Control.
 Standard serial port interface supports configuration of the device and customization for the user's needs.
- 5. 1.9 V or 3.3 V SPI and Serial Data Port Operation.

SPECIFICATIONS

Environmental	
Storage Temperature Range	–65°C to +125°C
Operating Temperature Range	–40°C to +85°C
Lead Temperature (Soldering, 10 sec)	300°C
Junction Temperature	150°C

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

THERMAL RESISTANCE

The exposed pad must be soldered to the ground plane for the LFCSP package. Soldering the exposed pad to the PCB increases the reliability of the solder joints, maximizing the thermal capability of the package.

Table 7.

14010 / 1			
Package Type	θ _{JA}	θ」	Unit
56-Lead LFCSP_VQ (CP-56-1)	23.7	1.7	°C/W

Typical θ_{IA} and θ_{JC} are specified for a 4-layer board in still air. Airflow increases heat dissipation, effectively reducing θ_{JA} . In addition, metal in direct contact with the package leads from metal traces, through holes, ground, and power planes reduces the θ_{JA} .

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

PIN CONFIGURATIONS AND FUNCTION DESCRIPTIONS

SPI REGISTER MAP

Table 10. Memory Map Register

Addr. (Hex)	Parameter Name	Bit 7 (MSB)	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0 (LSB)	Default Value (Hex)	Default Notes/ Comments
Chip Co	nfiguration Registers										
0x00	CHIP_PORT_CONFIG	0	LSB first	Soft reset	1	1	Soft reset	LSB first	0	0x18	The nibbles should be mirrored by the user so that LSB or MSB first mode registers correctly, regardless of shift mode.
0x01	CHIP_ID		8-bit chip ID, Bits[7:0] = 0xA0								Default is unique chip ID, different for each device. This is a read-only register.
0x02	CHIP_GRADE	0	0	Speed 10 = 50	grade: 0 MSPS	X ¹	X ¹	X ¹	X ¹	Read only	Child ID used to differentiate graded devices.
Transfer	Register								-		
0xFF	DEVICE_UPDATE		[7:1] = 0000000 SW transfer								Synchro- nously transfers data from the master shift register to the slave.
ADC Fui	nctions								•		
0x08	Modes	0	0	0	0	0	Interna 000 = nor 001	l power-down mal (power-u = full power-c 010 = standby 011 = reserve	n mode: p, default) lown V d	0x00	Determines various generic modes of chip operation.
0x0D		(For user- mode o Bits[3:0] 00 = Patte 01 = to Patte 10 = to Pattern 11 = to Pattern	edefined nly, set = 1000) rn 1 only oggle rn 1/ inrn 2 oggle 1/0000 oggle rn 1/ 2/0000	Reset PN23 gen: 1 = on 0 = off (default)	Reset PN9 gen: 1 = on 0 = off (default)	Output test mode: 0000 = off (default) 0001 = midscale short 0010 = +FS short 0011 = -FS short 0100 = checkerboard output 0101 = PN23 sequence 0110 = PN9 0111 = one/zero word toggle 1000 = user defined 1001 = unused 1010 = unused 1011 = unused 1010 = unused 1010 = unused 1000 = unused 0011 = unused 1000 = unused 0000 = unused 000 = un			0x00	When set, the test data is placed on the output pins in place of normal data. Set pattern values: Pattern 1: Reg 0x19, Reg 0x1A Pattern 2: Reg 0x1B Reg 0x1C.

THEORY OF OPERATION

The on-chip FIFO allows small snapshots of time to be captured via the ADC and read back at a lower rate. This reduces the constraints of signal processing by transferring the captured data at an arbitrary time and at a much lower sample rate.

FIFO OPERATION

The capture of the data can be signaled through writes to the SPI port by pulsing the FILL± pins. The transaction diagram shown in Figure 36 illustrates the loading of the FIFO.

At Event 1, the FIFO is instructed to fill either by asserting the FILL \pm pins or via a write to the SPI bits. FILL \pm pin operation can be delayed by a programmable fill hold-off counter so that the FIFO data can be surrounding a fill event. The FIFO then loads itself with data. The number of samples of data is determined by the SPI fill count register (0x104). This is an 8-bit register with values from 0 to 255. The number of samples placed in the FIFO is determined by the following equation:

Number of Samples = (*FILL_CNT* + 1) \times 64

After the FIFO has begun filling at Event 2, the AD6641 asserts a full flag to indicate that the FIFO has finished capturing data and enters a wait state in which the device waits to receive the dump instruction from the DUMP pin or the SPI.

After the data has been shifted (Event 4), the FIFO goes into the idle state and waits for another fill command. During the idle state, the ADC can optionally be placed into standby mode to save power. If the ADC powers down in the idle state, initiating a fill operation (Event 1) powers up the ADC. In this mode, the ADC waits for settle count cycles (0x105, 0x106) before capturing the data. Settle count is programmable from the SPI port and

allows the analog circuitry to stabilize before taking data. An intelligent trade-off between speed of acquisition and accuracy can be made by using this register.

The data can be read back through any of the three output interfaces at a low data rate, which further saves power. If the SPI or SPORT is used to read back the data, the interface can require as few as three pins. A full flag and an empty flag are provided to signal the state of the FIFO. The FIFO status register (0x10A) in the SPI also allows this to be monitored via software.

Single Capture Mode

The FIFO can be placed into single capture mode by writing the FIFO fill mode bits in the fill control register (0x101[3:2]) to 00. In the single capture mode, the user initiates a capture either by driving the FILL± pins high or by initiating a fill command through the SPI port by writing the standby after fill bit (0x101[0]). This powers up the ADC (if needed) after a programmable amount of time as determined by the SPI settle count registers (0x105, 0x106). If Bit 0 of the 0x101 register in the SPI is set, the ADC returns to standby mode after the capture is complete.

Fill Pin Timing

A fill of the FIFO can be initiated by asserting the differential FILL \pm pins. When a pulse is detected on the FILL \pm pins, the FIFO is filled.

Dump Pin Timing

A readback of the FIFO can be initiated by asserting the DUMP pin. When a logic high is detected on the DUMP pin, the FIFO data is available through the chosen interface.

SPORT Master Mode (Single Capture)

Details of the transaction diagram for serial master mode are shown in Figure 39 for single capture mode with the SDO output. Clock cycles are approximate because the fill and dump signals can be driven asynchronously. In this example, SCLK is derived from the master clock with a divide by 8 programmed from the SPI.

Fill Pulse (1)

The FIFO captures data after a fill signal (high level) is detected on the rising edge of the sampling clock. In synchronous operation, a valid high level is accomplished by adhering to the setup and hold times specified. For nonsynchronous control, the fill signal can be widened to accommodate two or more clock cycles to guarantee capture of a high level. Fill count (0x104) is reset on the rising edge of the clock and is incremented on subsequent clock cycles only after the fill signal returns low. A new fill signal at any point during the capture resets the counter and begins filling the FIFO.

Empty Signal (2)

After the FIFO state machine has begun loading data, the empty signal goes low 24 clock cycles after the fill signal was last sampled high.

Full Signal (3)

The full signal indicates when the FIFO has been filled and is driven high when the number of samples specified has been captured in the FIFO, where

Number of Samples = (*FILL_CNT* + 1) \times 64

The time at which the full signal goes high is based on (FILL_CNT + 1) \times 64 + 13 clock cycles after the fill signal was last sampled high.

Dump Signal (4)—Transition to High

The dump signal initiates reading data from the FIFO. Dump is enabled with a high level and should be initiated only after the full signal goes high. The dump signal should be held high until all data has been read out of the FIFO.

SCLK Signal (5)

The SCLK (serial clock) signal is configured as an output from the device when in the master mode of operation. SCLK begins cycling five ADC clock cycles after the dump signal is sampled high and continues cycling up until one additional cycle after the empty signal goes high. SCLK then remains low until the next dump operation.

SDFS Signal (6)

The SDFS (serial data frame sync) signal is configured as an output from the device when in the master mode of operation. Frame synchronization begins 15 ADC clock cycles after the dump signal is sampled.

Dump Signal (7)—Transition to Low

A dump signal transition to low is applied after data has been read out of the FIFO.

Empty Signal (8)—Transition to High

The empty signal transitions to high after data has been output from the FIFO based on the clock cycle count of (FILL_CNT + 1) × 64.

The transition occurs 76 ADC clock cycles after the last LSB(s) of data have been output on the serial port.

gure 39. SPORT Master Mode Transaction Diagrai

Parallel Master Mode (Single Capture)

Details of the transaction diagram for parallel master mode are shown in Figure 40 with the PD[11:0] output word. Clock cycles are approximate because the fill and dump signals can be driven asynchronously. In this example, PCLK± is derived from the master clock with a divide by 8 programmed from the SPI.

Fill Pulse (1)

The FIFO captures data after a fill signal (high level) is detected on the rising edge of the sampling clock. In synchronous operation, a valid high level is accomplished by adhering to the setup and hold times specified. For nonsynchronous control, the fill signal can be widened to accommodate two or more clock cycles to guarantee capture of a high level. Fill count (0x104) is reset on the rising edge of the clock and is incremented on subsequent clock cycles only after the fill signal returns low. A new fill signal at any point during the capture resets the counter and begins filling the FIFO.

Empty Signal (2)

After the FIFO state machine has begun loading data, the empty signal goes low 24 clock cycles after the fill signal was last sampled high.

Full Signal (3)

The full signal indicates when the FIFO has been filled and is driven high when the number of samples specified has been captured in the FIFO, where

Number of Samples = (*FILL_CNT* + 1) \times 64

The time at which the full signal goes high is based on (FILL_CNT + 1) \times 64 + 13 clock cycles after the fill signal was last sampled high.

Dump Signal (4)—Transition to High

The dump signal initiates reading data from the FIFO. Dump is enabled with a high level and should be initiated only after the full signal goes high. The dump signal should be held high until all data has been read out of the FIFO.

PCLK± Signal (5)

The PCLK± (parallel clock) signal is configured as an output from the device. PCLK± begins cycling 71 ADC clock cycles after the dump signal is sampled high. PCLK± goes low after the last data is read out of the FIFO and remains low until the next dump operation.

PD[11:0] Signal (6)

The PD (parallel data) output provides 12 data bits (PD[11:0]) at a maximum rate of $1/8^{th}$ of the sampling clock. Data begins after two PCLK± cycles (assuming the dump signal has been sampled).

Dump Signal (7)—Transition to Low

A dump signal transition to low is applied after data has been read out of the FIFO.

Empty Signal (8)—Transition to High

The empty signal transitions to high after data has been output from the FIFO based on the clock cycle count of (FILL_CNT + 1) \times 64. The transition occurs nine clock cycles after the last PCLK± rising edge.

Continuous Capture Mode

The FIFO can be placed into continuous capture mode by writing the FIFO fill mode bits in the fill control register (0x101[3:2]) to 01. In the continuous capture mode, data is loaded continuously into the FIFO and the FILL± pins pulsing high is used to stop the operation. This allows the history of the samples that preceded an event to be captured.

Figure 40. Parallel Mode Transaction Diagram

FIFO OUTPUT INTERFACES

The FIFO data is available through one of three interfaces. The data can be output on the serial data port (SPORT), the SPI port, or a 12-bit CMOS interface. The data port chosen must be selected from the SPI port before the data is read from the FIFO. Only one interface can be chosen at a time. The SPORT and SPI interfaces are powered via the SPI_VDDIO pin and can support either 1.9 V or 3.3 V logic levels.

SPORT Interface

The SPORT consists of a clock (SP_SCLK) and frame sync (SP_SDFS) signal. The SP_SCLK and SP_SDFS signals are output from the AD6641 when the SPORT is configured as a bus master and are input to the device when it is configured as a slave port.

Serial Data Frame (Serial Bus Master)

The serial data transfer is initiated with SP_SDFS. In master mode, the internal serial controller initiates SP_SDFS after the dump input goes high requesting the data. SP_SDFS is valid for one complete clock cycle prior to the data shift. On the next clock cycle, the AD6641 begins shifting out the data stream.

CMOS Output Interface

The data stored in the FIFO can also be accessed via a 12-bit parallel CMOS interface. The maximum output throughput supported by the AD6641 is in the 12-bit CMOS mode and is internally limited to 1/8th of the maximum input sample rate. Therefore, the output maximum output data rate is 62.5 MHz

at a 500 MSPS input sample rate. See Figure 3 for the parallel CMOS mode output interface timing diagram.

LVDS Output Interface

The AD6641 differential outputs conform to the ANSI-644 LVDS standard on default power-up. This can be changed to a low power, reduced signal option similar to the IEEE 1596.3 standard using the SPI. This LVDS standard can further reduce the overall power dissipation of the device, which reduces the power by ~39 mW. The LVDS driver current is derived on chip and sets the output current at each output equal to a nominal 3.5 mA. A 100 Ω differential termination resistor placed at the LVDS receiver inputs results in a nominal ±350 mV differential or 700 mV p-p swing at the receiver.

The AD6641 LVDS outputs facilitate interfacing with LVDS receivers in custom ASICs and FPGAs that have LVDS capability for superior switching performance in noisy environments. Single point-to-point net topologies are recommended with a 100 Ω termination resistor placed as close to the receiver as possible. No far-end receiver termination and poor differential trace routing may result in timing errors. It is recommended that the trace length be no longer than 24 inches and that the differential output traces be kept close together and at equal lengths.

The data on the LVDS output port is interleaved in a MSB/LSB format. PCLK \pm is generated by dividing the ADC sample clock by the programmed decimation rate (8 to 32, even divides). The maximum rate of PCLK \pm is limited to 62.5 MHz.

ANALOG INPUT AND VOLTAGE REFERENCE

The analog input to the AD6641 is a differential buffer. For best dynamic performance, match the source impedances driving VIN+ and VIN– such that common-mode settling errors are symmetrical. The analog input is optimized to provide superior wideband performance and requires that the analog inputs be driven differentially. SNR and SINAD performance degrades significantly if the analog input is driven with a singleended signal.

A wideband transformer, such as Mini-Circuits[®] ADT1-1WT, can provide the differential analog inputs for applications that require a single-ended-to-differential conversion. Both analog inputs are self-biased by an on-chip reference to a nominal 1.7 V.

An internal differential voltage reference creates positive and negative reference voltages that define the 1.5 V p-p fixed span of the ADC core. This internal voltage reference can be adjusted by means of an SPI control.

VREF

The AD6641 VREF pin (Pin 31) allows the user to monitor the on-board voltage reference or provide an external reference (requires configuration through the SPI). The three optional settings are internal V_{REF} (pin is connected to 20 k Ω to ground), export V_{REF} , and import V_{REF} . Do not attach a bypass capacitor to this pin. VREF is internally compensated and additional loading may impact performance.

CONFIGURATION USING THE SPI

Three pins define the SPI of the AD6641: SCLK, SDIO, and CSB (see Table 11). SCLK (a serial clock) is used to synchronize the read and write data presented from and to the AD6641. SDIO (serial data input/output) is a bidirectional pin that allows data to be sent to and read from the internal memory map registers. CSB (chip select) is an active low control that enables or disables the read and write cycles.

Pin	Function
SCLK	Serial clock. Serial shift clock input. SCLK is used to synchronize serial interface reads and writes.
SDIO	Serial data input/output. Bidirectional pin that serves as an input or an output, depending on the instruction being sent and the relative position in the timing frame.
CSB	Chip select (active low). This control gates the read and write cycles.

The falling edge of the CSB pin, in conjunction with the rising edge of the SCLK pin, determines the start of the framing. An example of the serial timing can be found in Figure 43 (for symbol definitions, see Table 5).

CSB can be held low indefinitely, which permanently enables the device; this is called streaming. CSB can stall high between bytes to allow additional external timing. When CSB is tied high, SPI functions are placed in high impedance mode.

During an instruction phase, a 16-bit instruction is transmitted. The first bit of the first byte in a serial data transfer frame indicates whether a read command or a write command is issued. Data follows the instruction phase, and its length is determined by the W0 and W1 bits. All data is composed of 8-bit words.

The instruction phase determines whether the serial frame is a read or write operation, allowing the serial port to be used both to program the chip and to read the contents of the on-chip memory. If the instruction is a read operation, the serial data input/output (SDIO) pin changes direction from an input to an output at the appropriate point in the serial frame.

Data can be sent in MSB first mode or in LSB first mode. MSB first is the default mode on power-up and can be changed via the SPI port configuration register. For more information about this and other features, see the AN-877 Application Note, *Interfacing to High Speed ADCs via SPI*.
